Microlocal sheaves and quiver varieties

ROMAN BEZRKAVNIKOV(1), MIKHAIL KAPRANOV(2)

À Vadim Schechtman pour son 60-ième anniversaire

RÉSUMÉ. – Nous relions les variétés de carquois de Nakajima aux espaces de modules des faisceaux pervers. Notamment, nous considérons une généralisation des faisceaux pervers: les faisceaux microlocaux sur une courbe nodale $X$. Ils sont définis comme les faisceaux pervers sur le normalisé de $X$ satisfaisant une condition sur la transformée de Fourier. Ils forment une catégorie abélienne $M(X)$. On a aussi une catégorie triangulée $DM(X)$ contenant $M(X)$. Pour $X$ compacte nous prouvons que $DM(X)$ est une catégorie de Calabi-Yau de dimension 2. Dans le cas où toutes les composantes irréductibles de $X$ sont rationnelles, $M(X)$ est équivalente à la catégorie des représentations de l’algèbre pré-projective multiplicative associée au graphe d’intersection de $X$. Les variétés de carquois proprement dites sont obtenues comme espaces de modules des faisceaux microlocaux munis d’une paramétrisation des cycles évanescents aux points singuliers. Dans le cas où les composantes de $X$ sont de genre supérieur, on obtient d’intéressantes généralisations des algèbres pré-projectives et des variétés de carquois. Nous les analysons du point de vue de la réduction pseudo-Hamiltonienne et des applications moment à valeurs dans un groupe.

ABSTRACT. – We relate Nakajima Quiver Varieties (or, rather, their multiplicative version) with moduli spaces of perverse sheaves. More precisely, we consider a generalization of the concept of perverse sheaves: microlocal sheaves on a nodal curve $X$. They are defined as perverse sheaves on normalization of $X$ with a Fourier transform condition near each node and form an abelian category $M(X)$. One has a similar triangulated category $DM(X)$ of microlocal complexes. For a compact $X$ we show that $DM(X)$ is Calabi-Yau of dimension 2. In the case when all components of $X$ are rational, $M(X)$ is equivalent to the category of representations of the multiplicative pre-projective algebra associated to the intersection graph of $X$. Quiver varieties in the proper sense are obtained as moduli
spaces of microlocal sheaves with a framing of vanishing cycles at singular points. The case when components of $X$ have higher genus, leads to interesting generalizations of preprojective algebras and quiver varieties. We analyze them from the point of view of pseudo-Hamiltonian reduction and group-valued moment maps.

## 0. Introduction

The goal of this paper is to relate two classes of symplectic manifolds of great importance in Representation Theory and to put them into a common framework.

**0.1 Moduli of local systems on Riemann surfaces.** First, let $X$ be a compact oriented $C^\infty$ surface and $G$ be a reductive algebraic group. The moduli space $LS_G(X)$ of $G$-local systems on $X$ is naturally a symplectic manifold [21], with the symplectic structure given by the cohomological pairing. As shown by Atiyah-Bott, $LS_G(X)$ can be obtained as the Hamiltonian reduction of an infinite-dimensional flat symplectic space formed by all $G$-connections, with the Lie algebra-valued moment map given by the curvature. Alternatively, $LS_G(X)$ can be obtained as a Hamiltonian reduction of a finite-dimensional symplectic space but at the price of passing to the multiplicative theory: replacing the Lie algebra-valued moment map by a group-valued one [3].

The variety $LS_G(X)$ and its versions associated to surfaces with punctures, marked points etc. form fundamental examples of cluster varieties [18], and their quantization is interesting from many points of view. We will
be particularly interested in the case \( G = GL_n \), in which case local systems form an abelian category.

(0.2) **Quiver varieties.** The second class is formed by the Nakajima quiver varieties [33]. Given a finite oriented graph \( Q \), the corresponding quiver varieties can be seen as symplectic reductions of the cotangent bundles to the moduli spaces of representations of \( Q \) with various dimension vectors. Passing to the cotangent bundle has the effect of “doubling the quiver”: introducing, for each arrow \( i \rightarrow j \) of \( Q \), a new arrow \( i \leftarrow j \) in the opposite direction.

Interestingly, one also has the “multiplicative” versions of quiver varieties defined by Crawley-Boevey and Shaw [14] and Yamakawa [45]. They can be constructed by performing the Hamiltonian reduction but using the group-valued moment map. It is these multiplicative versions that we will consider in this paper.

(0.3) **Relation to perverse sheaves.** It turns out that both these classes can be put under the same umbrella of *varieties arising from classification of perverse sheaves*.

From the early days of the theory [6], a lot of effort has been spent on finding descriptions of various categories of perverse sheaves as representation categories of some explicit quivers with relations. In all of these cases, the quivers have the following remarkable property: *their arrows come in pairs of opposites* \( i \leftarrow j \). This reflects the fact that any category of perverse sheaves has a perfect duality (Verdier duality). The diagram (representation of the quiver) corresponding to the dual perverse sheaf \( F^\star \) is obtained from the diagram corresponding to \( F \) by dualizing both the spaces and (up to a minor twist, cf. [29, (II.3.4)]) the arrows, thus interchanging the elements of each pair of opposites. We see therefore a conceptual reason for a possible relationship between perverse sheaves and quiver varieties.

The relation between perverse sheaves and \( LS_{GL_n}(X) \) is even more immediate: local systems are nothing but perverse sheaves without singularities, so “moduli spaces of perverse sheaves” are natural objects to look at.

(0.4) **Microlocal sheaves.** However, to make the above relations precise, we need to use a generalization of perverse sheaves: *microlocal sheaves*. These objects can be thought as modules over a (deformation) quantization of a symplectic manifold \( S \) supported in a given Lagrangian subvariety \( X \), see [24]. The case \( S = T^\star M \) being the cotangent bundle to a manifold \( M \) and \( X \) being conic, corresponds to the usual theory of holonomic \( \mathcal{D} \)-modules and
perverse sheaves. However, for our applications it is important to consider the case when \( X \) is compact.

In this paper we need only the simplest case when \( X \) is an algebraic curve over \( \mathbb{C} \) which is allowed to have nodal singularities. In this case microlocal sheaves can be defined in a very elementary way as perverse sheaves on the normalization satisfying a Fourier transform condition near each self-intersection point. The relation with quiver varieties appears when we take \( X \) to be a union of projective lines whose intersection graph is our “quiver” \( Q \) (with orientation ignored).

If we consider only “smooth” microlocal sheaves (no singularities other than the nodes), we get a natural analog of the concept of a local system for nodal curves. In particular, for a compact \( X \) we consider such microlocal sheaves as objects of a triangulated category \( D\mathcal{M}(X, \emptyset) \) of microlocal complexes, and we show in Thm. 1.7 that it has the 2-Calabi-Yau property, extending the Poincaré duality for local systems:

\[
R\text{Hom}(\mathcal{F}, \mathcal{G})^* \simeq R\text{Hom}(\mathcal{G}, \mathcal{F})[2].
\]

This gives an intrinsic reason to expect that the “moduli spaces” parametrizing microlocal sheaves or complexes, are symplectic, in complete analogy with Goldman’s picture [21] for local systems. We discuss the related issues in §5D and give a more direct construction of such spaces in §6 by using quasi-Hamiltonian reduction.

(0.5) **Relation to earlier work.** An earlier attempt to relate (multiplicative) quiver varieties and D-module type objects (i.e., to invoke the Riemann-Hilbert correspondence) was made by D. Yamakawa [45]. Although his construction is quite different from ours and is only applicable to quivers of a particular shape, it was one of the starting points of our investigation.

More recently, a Riemann-Hilbert type interpretation of multiplicative preprojective algebras was given by W. Crawley-Boevey [13]. His setup is in fact quite close to ours (although we learned of his paper only after most of our constructions have been formulated). In particular, the datum of a “Riemann surface quiver with non-interfering arrows”, a central concept of [13], is equivalent to the datum of a nodal curve \( X \): the normalization \( \tilde{X} \) is then the corresponding Riemann surface, and the pairwise identifications of the points of \( \tilde{X} \) needed to get \( X \), form a Riemann surface quiver. From our point of view, the construction of [13] can be seen as leading to an explicit description, in terms of D-module type data, of “smooth” microlocal sheaves on a nodal curve, see Theorem 2.3.
Considering a nodal curve $X$ as the basic object, has the advantage of putting the situation, at least heuristically, into the general framework of deformation quantization (DQ-)modules. In particular, one can consider for $X$ a projective curve with more complicated singularities, realized as a (necessarily Lagrangian) subvariety in a holomorphic symplectic surface. The general theory of [24] suggests that moduli spaces of “smooth” microlocal sheaves in this situation will produce interesting symplectic varieties. Further, passing to higher-dimensional projective singular Lagrangian varieties $X$, one expects to get shifted symplectic varieties, as suggested by the Calabi-Yau property of DQ-modules [24, Cor. 6.2.5] and the general theory of [25] and [34].

Our construction can be seen as a complex analog of the work of N. Sibilla, D. Treumann and E. Zaslow [36] who, among other things, associated some triangulated categories to 3 and 4 valent ribbon graphs by gluing microlocal data of real dimension 1.

We should also mention that symplectic manifolds related to the ones we construct, have appeared in the study of moduli spaces of Stokes data (irregular connections in dimension 1) [7][8][9]. In particular, [7] gives an interpretation of some of the Nakajima varieties as moduli spaces of Stokes data.

(0.6) Structure of the paper. In section 1 we define the category of microlocal sheaves on a nodal curve and establish its Calabi-Yau property. Section 2 discusses the De Rham counterpart of the topological definition of section 1. Section 3 is devoted to the twisting needed to account for the multiplicative analogue of a possibly nonzero moment value appearing in the definition of a Nakajima quiver variety. In section 4 we present the first version of our main result, Theorem 4.3, linking microlocal sheaves on a nodal curve with rational components to modules over the multiplicative preprojective algebra. In section 5 this is generalized to an arbitrary nodal curve, this leads to a new version of the multiplicative preprojective algebra which we call a higher genus preprojective algebra. Section 5 also contains remarks on construction and property of the moduli space of microlocal sheaves. In section 6 we discuss a multiplicative analogue of a Nakajima quiver variety; the additional data of a framing introduced by Nakajima corresponds here to a trivialization of the space of vanishing cycles at an additional smooth point of a curve where the sheaf is allowed to have a singularity. In contrast with Nakajima quiver varieties, the moduli spaces of framed (in the above sense) microlocal sheaves does not carry a natural symplectic form, it is rather a quasi-Hamiltonian space. This concept is
recalled and applied to the present context at the end of section 6. The final section 7 contains a discussion of further directions.

(0.7) Acknowledgements. We are grateful to A. Alekseev, P. P. Boalch, Y. Brunebarbe, T. Dyckerhoff, V. Ginzburg, P. Schapira, Y. Soibelman, G. Williamson and E. Zaslow for useful discussions and correspondence. We are particularly grateful to the referee for numerous remarks and suggestions that helped improve the paper. The work of R.B. was partly supported by an NSF grant and the Simons Foundation Fellowship. The work of M.K. was supported by the World Premier International Research Center Initiative (WPI), MEXT, Japan and by the Max-Planck Institute für Mathematik, Bonn, Germany.

1. Microlocal sheaves on nodal curves

A. Topological definitions

Let $X$ be a nodal curve over $\mathbb{C}$, i.e., an algebraic, quasi-projective curve whose only singularities are transversal self-intersection points (also known as nodes, or ordinary double points).

For a node $x \in X$ we denote two “branches” of $X$ near $x$ (defined up to permutation) by $B'$ and $B''$. More precisely, we think of $B'$ and $B''$ as small disks meeting at $x$. Alternatively, let $\tilde{\omega} : \tilde{X} \to X$ be the normalization of $X$. Then $\tilde{\omega}^{-1}(x) = \{x', x''\}$ consists of two points, and we define $\tilde{B}', \tilde{B}''$ as the neighborhoods of $x'$ and $x''$ in $\tilde{X}$. We can then identify canonically $B' = \tilde{B}', B'' = \tilde{B}''$. We note that the Zariski tangent space to $X$ at a node $x$ is 2-dimensional:

$$T_x X = T_x B' \oplus T_x B''.$$  

Definition 1.1. — A duality structure on $X$ is a datum, for each node $x$, of a symplectic structure $\omega_x$ on the 2-dimensional vector space $T_x X$.

Alternatively, a duality structure at a node $x$ can be considered as a datum of isomorphisms

$$\varepsilon'_x : T_x B' \to T_x B'', \quad \varepsilon''_x : T_x B'' \to T_x B'$$

such that $(\varepsilon''_x)^* = -\varepsilon'_x$.

Example 1.2. — (a) Suppose $X$ embedded into a holomorphic symplectic surface $(S, \omega)$. Then the restrictions of $\omega$ to all the nodes of $X$ give a duality structure on $X$.  

- 478 -
Note that any duality structure on \( X \) can be obtained in this way. Indeed, we first consider a neighborhood \( \tilde{S} \) of the zero section in the cotangent bundle \( T^*\tilde{X} \). Then for any node \( x \in X \) with \( \varpi^{-1}(x) = \{x', x''\} \), we identify the neighborhoods \( U' \) of \( x' \) and \( U'' \) of \( x'' \) in \( \tilde{S} \) by an appropriate symplectomorphism so that the intersection of \( U' \) with the zero section of \( T^*\tilde{S} \) becomes identified with the intersection of \( U'' \) with the fiber of \( T^*\tilde{S} \) over \( x'' \) and vice versa.

(b) Situations when \( X \) is naturally embedded into an algebraic symplectic surface \( S \), provide a richer structure. The best known examples are provided by \( S \) being the minimal resolution of a Kleinian singularity \( \mathbb{C}^2/G \), where \( G \) is a finite subgroup in \( SL_2(\mathbb{C}) \). In this case \( X \) is a union of projective lines, with the intersection graph being a Dynkin diagram of type ADE.

Let \( X \) be a nodal curve with a duality structure. For each node \( x \in X \) we can identify \( B' \) and \( B'' \) with open disks in \( T_x B' \) and \( T_x B'' \) or, equivalently, in \( T_x \tilde{B}' \) and \( T_x \tilde{B}'' \) respectively. Such identifications are unique up to contractible spaces of choices.

Let \( D^b(\tilde{B}'', x'') \) be the full subcategory in \( D^b_{\text{constr}}(\tilde{B}'') \) formed by complexes whose cohomology sheaves are locally constant outside \( x'' \), and similarly for \( D^b(\tilde{B}'', x'') \). Let \( \text{Perv}(\tilde{B}', x') \subset D^b(\tilde{B}', x') \) and \( \text{Perv}(\tilde{B}'', x'') \subset D^b(\tilde{B}'', x'') \) be the full (abelian) subcategories formed by perverse sheaves.

The above identifications with the disks in the tangent spaces together with the isomorphisms \( \varepsilon', \varepsilon'' \) give rise to geometric Fourier(-Sato) transforms which are equivalences of pre-triangulated categories

\[
D^b(\tilde{B}', x') \xrightarrow{\text{FT}'} \xleftarrow{\text{FT}''} D^b(\tilde{B}'', x''),
\]

which are canonically inverse to each other and restrict to equivalence of abelian categories

\[
\text{Perv}(\tilde{B}', x') \xrightarrow{\text{FT}'} \xleftarrow{\text{FT}''} \text{Perv}(\tilde{B}'', x'').
\]

Remark 1.3. — The fact that \( \text{FT}' \) and \( \text{FT}'' \) are precisely inverse to each other, comes from the requirement that \( \varepsilon'_x \) and \( \varepsilon''_x \) are the negatives of the transposes of each other, rather than exact transposes. We recall that the “standard” Fourier-Sato transform for a \( \mathbb{C} \)-vector space \( E \) is an equivalence ([23], Ch. 3)

\[
\text{FT}_E : D^b_{\text{mon}}(E) \to D^b_{\text{mon}}(E^*)
\]
(\(D^b_{\text{mon}}\) means the derived category of \(\mathbb{C}\)-monodromic constructible complexes). In this setting \(\text{FT}_E^*\) is not canonically inverse to \(\text{FT}_E\): the composition \(\text{FT}_E^* \circ \text{FT}_E\) is canonically identified with \((-1)^*\), the pullback with respect to the antipodal transformation \((-1): E \to E\).

**Definition 1.4.** — A microlocal complex \(\mathcal{F}\) on \(X\) is a datum consisting of:

1. A \(\mathbb{C}\)-constructible complex \(\tilde{\mathcal{F}}\) on \(\tilde{X}\).
2. For each node \(x \in X\), quasi-isomorphisms of constructible complexes
   \[
   \alpha' : \tilde{\mathcal{F}}|_{\tilde{B}'} \to \text{FT}''(\tilde{\mathcal{F}}|_{\tilde{B}'}) , \quad \alpha'' : \tilde{\mathcal{F}}|_{\tilde{B}''} \to \text{FT}'(\tilde{\mathcal{F}}|_{\tilde{B}'}) ,
   \]
   inverse to each other.

A microlocal sheaf on \(X\) is a microlocal complex \(\mathcal{F}\) such that \(\tilde{\mathcal{F}}\) is a perverse sheaf on \(\tilde{X}\).

A morphism of microlocal complexes (resp. microlocal sheaves) \(\mathcal{F} \to \mathcal{G}\) is a morphism of constructible complexes (resp. perverse sheaves) \(\tilde{\mathcal{F}} \to \tilde{\mathcal{G}}\) on \(\tilde{X}\) compatible with the identifications \(\alpha', \alpha''\). In this way we obtain a pre-triangulated category \(DM(X)\) formed by microlocal complexes on \(X\) and an abelian subcategory \(M(X)\) formed by microlocal sheaves.

For a finite subset of smooth points \(A \subset X_{\text{sm}}\) we denote by \(DM(X, A) \subset DM(X)\) the full subcategory formed by microlocal complexes \(\mathcal{F}\) such that \(\tilde{\mathcal{F}}\) is smooth (i.e., each cohomology sheaf of it is a local system) outside of \(\varpi^{-1}(A)\). Let \(M(X, A)\) be the intersection of \(M(X)\) with \(DM(X, A)\).

**Remarks 1.5.** — (a) Suppose \(k = \mathbb{C}((h))\) is the field of Laurent series in one variable \(h\) with complex coefficients. Assume that \(X\) is embedded into a symplectic surface \((S, \omega)\), as in Example 1.2. As shown in [24], \(S\) admits a deformation quantization algebroid \(A_S\), which locally can be viewed as a sheaf of \(\mathbb{C}[[h]]\)-algebras whose reduction modulo \(h\) is identified with \(\mathcal{O}_S\) and whose first order commutators are given by the Poisson bracket of \(\omega\). One also has the \(h\)-localized algebroid \(A_S^{\text{loc}} = A_S \otimes_{\mathbb{C}[h]} \mathbb{C}((h))\).

The category \(DM(X, \emptyset)\) can be compared with the category \(D^{b}_{\text{gd}, X}(A_S^{\text{loc}})\) of complexes of \(A_S^{\text{loc}}\)-modules whose cohomology modules are coherent, algebraically good [24, 2.7.2] modules supported on \(X\). More precisely, each smooth (not necessarily closed) Lagrangian \(\mathbb{C}\)-submanifold (i.e., a smooth complex curve) \(\Lambda \subset S\), gives a simple holonomic \(A_X^{\text{loc}}\)-module \(\mathcal{O}_\Lambda\), and we
have the “Λ-Riemann-Hilbert functor”
\[ R\text{Hom}_{A_{\text{loc}}^\text{S}}(\Lambda, O_\Lambda) : D^b_{gd,X}(A_{\text{loc}}^\text{S}) \to D^b_{\text{const}}(\Lambda). \]

Taking for Λ various smooth branches of X, we associate to an object N of \( D^b_{gd,X}(A_{\text{loc}}^\text{S}) \) a constructible complex \( \tilde{F} \) on \( \tilde{X} \). If \( N \) is a single module in degree 0, then \( \tilde{F} \) is a perverse sheaf. When two branches meet at a point (node \( x \) of \( X \)), the corresponding Riemann-Hilbert functors are, near \( x \), related to each other by the Fourier transform, thus leading to Definition 1.4.

(b) A particularly interesting algebraic case is provided by \( S \) being the minimal resolution of a Kleinian singularity, see Example 1.2(b). In this case quantizations of \( S \) exist algebraically in finite form (not just over power series in \( h \)), see [11]. It is therefore interesting to compare their modules with microlocal sheaves on Dynkin chains of \( \mathbb{P}^1 \)'s.

Let \( X \) be a nodal curve with duality structure and \( A \subset X_{\text{sm}} \) a finite subset of smooth points. Let us form a new, noncompact nodal curve
\[ X_A = X \cup \bigcup_{a \in A} T_a^*X \]
by attaching each cotangent line \( T_a^*X \) to \( X \) at the point \( a \) which becomes a new node. The symplectic structure on \( T^*X_{\text{sm}} \) gives a duality structure at each new node.

PROPOSITION 1.6. — We have canonical equivalences
\[ DM(X, A) \simeq DM(X_A, \emptyset), \quad \mathcal{M}(X, A) \simeq \mathcal{M}(X_A, \emptyset). \]

Proof. — We identify the normalization of \( X_A \) as
\[ \tilde{X}_A = \tilde{X} \sqcup \bigcup_{a \in A} T^*_aX. \]
To each microlocal complex \( \mathcal{F} \) on \( X \) we associate a microlocal complex \( \mathcal{F}_A \) on \( X_A \) given by
\[ \mathcal{F}_A|_{\tilde{X}} = \mathcal{F}, \quad \mathcal{F}_A|_{T^*_aX} = \mu_a(\mathcal{F}), \]
where \( \mu_a(\mathcal{F}) \) is the microlocalization of \( \mathcal{F} \) at \( a \), i.e., the Fourier transform of the specialization of \( \mathcal{F} \) at \( a \) [23]. The definition gives the Fourier transform identifications for \( \mathcal{F}_A \). This defines the desired equivalence. □
B. The Calabi-Yau property

Important for us will be the following.

**Theorem 1.7.** — Let $X$ be a compact nodal curve over $\mathbb{C}$ equipped with a duality structure. Then $\mathcal{D}M(X, \emptyset)$ is a Calabi-Yau dg-category of dimension 2. In other words, for any $\mathcal{F}, \mathcal{G} \in \mathcal{D}M(X, \emptyset)$ we have a canonical quasi-isomorphism of complexes of $k$-vector spaces

$$R\text{Hom}(\mathcal{F}, \mathcal{G})^* \simeq R\text{Hom}(\mathcal{G}, \mathcal{F})[2].$$

**Example 1.8.** — For $X$ smooth, the category $\mathcal{M}(X, \emptyset)$ consists of local systems on $X$, and $\mathcal{D}M(X)$ consists of complexes with locally constant cohomology. Theorem 1.7 in this case reduces to the Poincaré duality for local systems on a compact oriented topological surface.

**Remark 1.9.** — Consider the situation of Remark 1.5(a). For a compact symplectic manifold $S$ of any dimension $d$, Corollary 6.2.5 of [24] gives that $D^b_{\text{gd}}(\mathcal{A}^\text{loc}_S)$, the category of all complexes of $\mathcal{A}^\text{loc}_S$-modules with coherent and algebraically good cohomology, is a Calabi-Yau category over $\mathbb{C}((h))$ of dimension $d$. This result can be seen as a noncommutative lifting of the classical Serre duality for coherent $\mathcal{O}_S$-modules.

If $S$ is non-compact, then restricting the support to a given compact subvariety $X$ allows one to preserve the duality, cf. [24, Cor. 3.3.4]. In particular, when $S$ is a symplectic surface, and $X \subset S$ is a compact nodal curve, $D^b_{\text{gd}, X}(\mathcal{A}^\text{loc}_S)$ is a Calabi-Yau category over $\mathbb{C}((h))$ of dimension 2. Our Theorem 1.7 can be seen as a topological analog of this fact.

**Proof of Theorem 1.7.** — Let $\mathcal{F}, \mathcal{G} \in \mathcal{D}M(X, \emptyset)$. For any open set $U \subset X$ (in the classical topology) we have the complex of vector spaces

$$R\text{Hom}_{\mathcal{D}M(U, \emptyset)}(\mathcal{F}|_U, \mathcal{G}|_U) \in D^b\text{Vect}_k.$$

Taken for all $U$, these complexes can be thought as forming a complex of sheaves which we denote

$$\mathcal{M}\text{Hom}(\mathcal{F}, \mathcal{G}) \in D^b_{\text{constr}}(X),$$

so that, in a standard way, we have

$$R\text{Hom}_{\mathcal{D}M(X, \emptyset)}(\mathcal{F}, \mathcal{G}) = R\Gamma(X, \mathcal{M}\text{Hom}(\mathcal{F}, \mathcal{G})).$$

Our statement will follow from the Poincaré-Verdier duality on the compact space $X$, if we establish the following.

**Proposition 1.10.** — For any nodal curve $X$ (compact or not) with duality structure and any microlocal complexes $\mathcal{F}, \mathcal{G} \in \mathcal{D}M(X, \emptyset)$ we have a canonical identification

$$\mathbb{D}_X \mathcal{M}\text{Hom}(\mathcal{F}, \mathcal{G}) \simeq \mathcal{M}\text{Hom}(\mathcal{G}, \mathcal{F})[2].$$
To prove the proposition, we compare the bifunctor $\mathcal{M}\text{Hom}$ with the microlocal Hom bifunctor of [23] which we recall.

Let $M$ be a smooth manifold and $\pi : T^*M \to M$ be its cotangent bundle. For any two complexes of sheaves $F, G$ on $M$. Kashiwara and Schapira [23] defined a complex of sheaves

$$\mu\text{Hom}(F, G) \in D^b\text{Sh}_{T^*M}$$

so that

$$R\text{Hom}(F, G) = R\pi_* (\mu\text{Hom}(F, G)),$$

$$R\text{Hom}_{D^b\text{Sh}_M}(F, G) = R\Gamma(T^*M, \mu\text{Hom}(F, G)).$$

**Lemma 1.11.** — Assume that $M$ is a complex manifold and $F, G \in D^b_{\text{constr}}(M)$. Then we have a canonical identification

$$\mathbb{D}_{T^*M}(\mu\text{Hom}(F, G)) \simeq \mu\text{Hom}(G, F).$$

**Proof.** — This is a particular case of Proposition 8.4.14(ii) of [23].

We now deduce Proposition 1.10 from Lemma 1.11.

**Definition 1.12.** — Call a subset $Z \subset X$ unibranched, if $Z$ is the image, under the normalization map $\varpi : \tilde{X} \to X$, of an open (in the classical topology) subset $\tilde{Z}$ such that the restriction $\varpi|_\tilde{Z} : \tilde{Z} \to Z$ is a bijection.

Note that a unibranched subset $Z$ is a complex analytic curve which may not be open in $X$, if it passes through some nodes (in which case it contains only one branch near each node it passes through). For a microlocal complex $\mathcal{F}$ on $X$ and a unibranched $Z \subset X$ we have a well-defined constructible complex

$$\mathcal{F}|_Z := (\varpi|_\tilde{Z})_* \tilde{\mathcal{F}} \in D^b_{\text{constr}}(Z).$$

Assume that $X$ is embedded into a symplectic surface $S$ and let $U$ be a neighborhood of $Z$ in $S$. Then we can make the following identifications:

1. $U$ can be identified with a neighborhood of $Z$ in $T^*Z$ so that $Z$ becomes identified with the zero section $T^*_Z Z$.
2. If we denote the nodes of $X$ contained in $Z$, by $x_i, i \in I$, then $U \cap Z$ can be identified with the union of $T^*_Z Z$ and of some neighborhoods of 0 in the fibers $T^*_{x_i} Z$.
3. Let $\mathcal{F}, \mathcal{G}$ be two microlocal complexes on $X$. Then, under the above identifications, we have an isomorphism

$$\mathcal{M}\text{Hom}(\mathcal{F}, \mathcal{G})|_{U \cap Z} \simeq \mu\text{Hom}(\mathcal{F}|_Z, \mathcal{G}|_Z)|_{U \cap Z}.$$
Further, because of the Fourier transform identifications in the definition of a microlocal complex, the identifications in (3) are compatible for different unibranched sets passing through a given node. Therefore the identifications (3) allow us to glue the identifications of Lemma 1.11 to a canonical identification as in Proposition 1.10. This proposition and Theorem 1.7 are now proved.

We now give a $\mathcal{D}$-module type description of microlocal sheaves, relating our approach with that of [13].

A. Formulations

Let $X$ be a nodal curve with the set of nodes $D$ and its preimage $\tilde{D} = \varpi^{-1}(D) \subset \tilde{X}$. By an orientation of $X$ we mean a choice, for each node $x$, of the order $(x' < x'')$ on the two element set of preimages $\varpi^{-1}(x) = \{x', x''\}$.

We denote by
\[ \mathbb{R}^{-1}[0, 1) = [0, 1) + i\mathbb{R} \subset \mathbb{C} \]
the standard fundamental domain for $\mathbb{C}/\mathbb{Z}$.

Let $Y$ be a smooth algebraic curve over $\mathbb{C}$ (not necessarily compact) and $Z \subset Y$ a finite subset. We recall, see, e.g. [29], the concept of a logarithmic connection (along $Z$) on an algebraic vector bundle $\mathcal{E}$ on $Y$. Such a connection $\nabla$ can be viewed as an algebraic differential operator $\nabla : \mathcal{E} \to \mathcal{E} \otimes \Omega^1_Y(\log Z)$. It has a well-defined residue $\text{Res}_z(\nabla) \in \text{End}(\mathcal{E}_z)$ at each $z \in Z$. For a noncompact $Y$ there is a concept of a regular logarithmic connection (having regular singularities at the infinity of $Y$).

**Definition 2.1.** — Let $X$ be a nodal curve over $\mathbb{C}$, not necessarily compact, with orientation. A de Rham microlocal sheaf (without singularities) on $X$ is a datum of:

1. A vector bundle $\mathcal{E}$ on $\tilde{X}$, together with a regular logarithmic connection $\nabla$ along $\tilde{D}$.
2. For each node $x \in D$ with preimages $x', x'' \in \tilde{D}$ (order given by the orientation), two linear operators
\[ \mathcal{E}_{x'} \xrightarrow{u_x} \mathcal{E}_{x''} \]
\[ \mathcal{E}_{x'} \xleftarrow{v_x} \mathcal{E}_{x''} \]
such that:
(3) $\text{Res}_{x'}(\nabla) = v_x u_x$, $\text{Res}_{x''}(\nabla) = -u_x v_x$;
(4) All eigenvalues of $v_x u_x$ and $-u_x v_x$ lie in $\mathbb{R}^{-1}[0,1)$.

The category of de Rham microlocal sheaves on $X$ without singularities will be denoted by $\mathcal{M}_{\text{dR}}(X, \emptyset)$.

**Remarks 2.2.** — A de Rham microlocal sheaf is a particular case ($\lambda = 0$) of a $\lambda$-connection system of [13], but with additional restriction (4). We note that the concept of a “$\lambda$-connection system” should not be confused with that of a “$\lambda$-connection” introduced by Deligne and Simpson which is a completely different notion.

**Theorem 2.3.** — Take the base field $k = \mathbb{C}$. Assume that $X$ is equipped with both an orientation and a duality structure. Then $\mathcal{M}_{\text{dR}}(X, \emptyset)$ is equivalent to $\mathcal{M}(X, \emptyset)$.

**B. Riemann-Hilbert correspondence**

In order to prove Theorem 2.3, we recall two classical results about the Riemann-Hilbert correspondence.

First, let $Y$ be a smooth curve over $\mathbb{C}$ and $Z \subset Y$ a finite subset. A regular logarithmic connection $\nabla : \mathcal{E} \to \mathcal{E} \otimes \Omega^1_Y(\log Z)$ will be called *canonical*, all eigenvalues of all $\text{Res}_z(\nabla)$, $z \in Z$, lie in $\mathbb{R}^{-1}[0,1)$. In this case $(\mathcal{E}, \nabla)$ is obtained by the Deligne canonical extension from its restriction to $Y - Z$, see [29]. We denote by $\text{Conn}^\text{reg can}(Y, Z)$ the category of vector bundles with regular canonical connections.

**Proposition 2.4.** — The category $\text{Conn}^\text{reg can}(Y, Z)$ is equivalent to $\text{LS}(Y - Z)$, the category of local systems on $Y - Z$. The equivalence is obtained by restricting $(\mathcal{E}, \nabla)$ to $Y - Z$ and taking the sheaf of covariantly constant sections.

**Proposition 2.5.** [22][29, (II.2.1)]. — Let $\mathcal{I}$ be the category of diagrams of finite-dimensional $\mathbb{C}$-vector spaces

$$H = \{ E \xrightarrow{u} F \}$$

s.t. all eigenvalues of $uv$ and $(-vu)$ lie in $\mathbb{R}^{-1}[0,1)$. Then $\mathcal{I}$ is equivalent to $\text{Perv}(\mathbb{C}, 0)$. The equivalence takes an object $H \in \mathcal{I}$ to the $\mathcal{D}_{\mathbb{C}}$-module $M_H$ with the space of generators $E \oplus F$ and relations

$$x \cdot f = v(f), \ f \in F,$$

$$\frac{d}{dx} \cdot e = u(e), \ e \in E,$$

and then to the de Rham complex of $M_H$. □
C. Fourier transform and RH

Recall [29] that the Fourier-Sato transform on $\text{Perv}(\mathbb{C}, 0)$ corresponds, at the $\mathcal{D}$-module level, to passing from the generators $x, \frac{d}{dx}$ of the Weyl algebra of differential operators to new generators

$$p = -\frac{d}{dx}, \quad \frac{d}{dp} = x,$$

so that

$$\left[ \frac{d}{dp}, p \right] = \left[ \frac{d}{dx}, x \right] = 1.$$  

This implies:

**Corollary 2.6.** — The effect of the Fourier-Sato transform on $\mathcal{I}$ is the functor

$$\text{FT}_{\mathcal{I}} : H = \{ E \xrightarrow{u} F \} \mapsto \hat{H} = \{ F \xrightarrow{v} E \}.$$  

Therefore we can reformulate Proposition 2.5 in a more "microlocal" form

**Proposition 2.7.** — Let $C = \{ xp = 0 \} \subset \mathbb{C}^2$ be the coordinate cross with the orientation defined by putting the $x$-branch before the $p$-branch. Then $\mathcal{M}_{\text{dR}}(C, \emptyset)$ is equivalent to $\text{Perv}(\mathbb{C}, 0) \simeq \mathcal{M}(C, \emptyset)$. Here the last identification is given in Proposition 1.6.

**Proof.** — For a diagram $H \in \mathcal{I}$, the $\mathcal{D}_C$-module $M_H$ becomes $\mathcal{O}$-coherent on $\mathbb{C} - \{0\}$, and is identified with the following bundle with connection:

$$\mathcal{E}^0_H = \left( E \otimes \mathcal{O}_{\mathbb{C} - \{0\}}, \nabla = d - (vu)\frac{dx}{x} \right).$$

Therefore the Deligne canonical extension of $\mathcal{E}^0_H$ to $\mathbb{C}$ is the logarithmic connection

$$\mathcal{E}_H = \left( E \otimes \mathcal{O}_\mathbb{C}, \nabla = d - (vu)\frac{dx}{x} \right).$$

Similarly for the Fourier transformed diagram $\hat{H}$ which gives a bundle with logarithmic connection on $\mathbb{C}$ which we view as the other branch of $C$ with coordinate $p$:

$$\mathcal{E}_{\hat{H}} = \left( F \otimes \mathcal{O}_\mathbb{C}, \nabla = d + (uv)\frac{dp}{p} \right).$$

This means that the data $(\mathcal{E}_H, \mathcal{E}_{\hat{H}}, u, v)$ form an object of $\mathcal{M}_{\text{dR}}(C, \emptyset)$. So we get a functor $\mathcal{I} \to \mathcal{M}_{\text{dR}}(C, \emptyset)$. The fact that it is an equivalence, is verified in a standard way. □
Theorem 2.3 is now obtained by gluing together the descriptions given by Proposition 2.4 over $X_{\text{sm}}$ and by Proposition 2.5 near the nodes of $X$. □

3. Twisted microlocal sheaves

A. Motivation: twisted $\mathcal{D}$-modules and sheaves

Let $X$ be a smooth algebraic variety over $\mathbb{C}$. We recall [5] that to each class $t \in H^1_{\text{Zar}}(X, \{ \Omega_X^1 \overset{d}{\to} \Omega_X^{2,\text{cl}} \})$ there corresponds a sheaf of rings of twisted differential operators on $X$ which we denote $\mathcal{D}_X^t$.

Recall further that the first Chern class can be understood as a homomorphism

$$c_1 : \text{Pic}(X) \longrightarrow H^1_{\text{Zar}}(X, \{ \Omega_X^1 \overset{d}{\to} \Omega_X^{2,\text{cl}} \}).$$

If $\mathcal{L}$ is a line bundle on $X$, then we have an explicit model:

$$\mathcal{D}_{\mathcal{L}}^{c_1(L)} = \text{Diff}(\mathcal{L}, \mathcal{L})$$

is the sheaf formed by differential operators from sections of $\mathcal{L}$ to sections of $\mathcal{L}$. For a compact $X$, the image of $c_1$ is typically an integer lattice in a complex vector space and the sheaves $\mathcal{D}_X^t$ can be seen as interpolating between the $\text{Diff}(\mathcal{L}, \mathcal{L})$ for different $\mathcal{L}$. We recall a particular explicit instance of this interpolation.

Given a line bundle $\mathcal{L}$ on $X$, we denote by $\mathcal{L}^\circ$ the total space of $\mathcal{L}$ minus the zero section, so $p : \mathcal{L}^\circ \to X$ is a $\mathbb{C}^*$-torsor over $X$. We denote by $\theta$ the Euler vector field “$x \partial/\partial x$” on $\mathcal{L}^\circ$, i.e., the infinitesimal generator of the $\mathbb{C}^*$-action. Thus $\theta$ is a global section of $\mathcal{D}_{\mathcal{L}^\circ}$.

Proposition 3.1. — Let $\lambda \in \mathbb{C}$. Then

$$\mathcal{D}_{\mathcal{L}^\circ}^{c_1(\mathcal{L})} \simeq p_* \left( \mathcal{D}_{\mathcal{L}^\circ} / \mathcal{D}_{\mathcal{L}^\circ}(\theta - \lambda) \mathcal{D}_{\mathcal{L}^\circ} \right).$$

We now discuss the consequences of Proposition 3.1 for the Riemann-Hilbert correspondence for twisted $\mathcal{D}$-modules.

On the $\mathcal{D}$-module side, the concepts of holonomic and regular $\mathcal{D}_X^t$-modules are defined in the same way as in the untwisted case. We denote by $\mathcal{D}_X^t - \text{Mod}_{h.r.}$ the category of holonomic regular $\mathcal{D}_X^t$-modules, and by $D^b_{h.r.}(\mathcal{D}_X^t - \text{Mod})$ the derived category formed by complexes with holonomic regular cohomology modules.
On the sheaf side, choose $q \in k^*$. Let $\mathcal{L}$ be a line bundle on $X$. We denote by $\text{Sh}^{\mathcal{L},q}(X)$ the category of sheaves on $\mathcal{L}$ whose restriction on each fiber of $p$ is a local system with scalar monodromy $q \cdot \text{Id}$. Let $D^b(X)^{\mathcal{L},q}$ be the bounded derived category of $\text{Sh}^{\mathcal{L},q}(X)$. We denote by $D^b_{\text{constr}}(X)^{\mathcal{L},q}$ the full subcategory formed by complexes with $\mathbb{C}$-constructible cohomology sheaves, and $\text{Perv}^{\mathcal{L},q}(X) \subset D^b_{\text{constr}}(X)^{\mathcal{L},q}$ the full subcategory of perverse sheaves.

Proposition 3.1 implies the following.

**Corollary 3.2.** — Take the base field $k = \mathbb{C}$. Let $\mathcal{L}$ be a line bundle on $X$ and $\lambda \in \mathbb{C}$. We have an anti-equivalence of (pre-)triangulated categories and a compatible anti-equivalence of abelian categories

$$D^b_{\text{h.r.}}(\mathcal{D}X^{\lambda_1}(\mathcal{L}) - \text{Mod}) \to D^b_{\text{constr}}(X)^{\mathcal{L},e^{2\pi i \lambda}}, \mathcal{D}X^{\lambda_1}(\mathcal{L}) - \text{Mod}_{\text{h.r.}} \to \text{Perv}^{\mathcal{L},e^{2\pi i \lambda}}(X).$$

**Remark 3.3.** — For example, if $\lambda = n$ is an integer, then the monodromy comes out to be trivial, and we get that $\mathcal{D}X^{\lambda_1}(\mathcal{L}) - \text{Mod}_{\text{h.r.}}$ is anti-equivalent to $\text{Perv}_X$. This can also be seen directly, as $D^{nc_1}(\mathcal{L}) = \text{Diff}(\mathcal{L} \otimes n, \mathcal{L} \otimes n)$ and so we have the “solution functor” associating to any module $\mathcal{M}$ over this sheaf of rings the complex

$$\text{Sol}(\mathcal{M}) = R\text{Hom}_{\text{Diff}(\mathcal{L} \otimes n, \mathcal{L} \otimes n)}(\mathcal{M}, \mathcal{L} \otimes n).$$

This complex is perverse, and the functor Sol establishes the desired anti-equivalence.

We will also consider the “universal twist” situation by not requiring the monodromy to be a fixed scalar multiple of 1 and working instead with monodromic sheaves and complexes on $\mathcal{L}^\circ$.

That is, we consider the derived category $D^b_{\text{mon}}(\mathcal{L}^\circ)$ defined as the full subcategory in $D^b_{\text{Sh}}(\mathcal{L}^\circ)$ formed by $\mathbb{C}$-monodromic complexes. Inside it, let $D^b_{\text{constr}}(X)^{\mathcal{L}}$ be the full triangulated subcategory of $\mathbb{C}$-constructible $\mathbb{C}$-monodromic complexes and $\text{Perv}(X)^{\mathcal{L}}$ the abelian subcategory of perverse sheaves on $\mathcal{L}^\circ$ which are $\mathbb{C}$-monodromic.

Note that the natural functor $D^b(X)^{\mathcal{L},q} \to D^b_{\text{constr}}(X)^{\mathcal{L}}$ is not fully faithful. In the $\mathcal{D}$-module picture this corresponds to the fact that the derived pullback functor on modules corresponding to the projection of sheaves of rings $\mathcal{D}_{\mathcal{L}^\circ} \to \mathcal{D}_{\mathcal{L}^\circ}/(\theta - \lambda)$ is not fully faithful.

**B. Twisted microlocal sheaves**

We now modify the above and apply it to the case when $X$ is a nodal curve.
So let $X$ be a nodal curve over $\mathbb{C}$ with the normalization map $\varpi : \tilde{X} \to X$, as in §1. We denote by $D \subset X$ the set of nodes, and by $\tilde{D} \subset X$ its preimage under $\varpi$. For any node $x$ we choose a small analytic neighborhood $U = U_x = B' \cup_x B''$ of $x$. Here $B', B''$ are two branches of $X$ near $x$ which we identify with their preimages $\tilde{B}', \tilde{B}'' \subset \tilde{X}$.

Let $L$ be a line bundle on $X$. We denote by $\tilde{L} = \varpi^*(L)$ its pullback to $\tilde{X}$ and by $\tilde{p} : \tilde{\mathcal{L}} \to \tilde{X}$ the projection. For each node $x$ we choose an almost-trivialization of $L$ over $U_x$, by which we mean an identification of $L|_{U_x}$ with the trivial line bundle with fiber $L_x$ or, equivalently, an identification of $\mathbb{G}_m$-torsors $L|_{U_x} \to U_x \times L_x$. (Note that the space of almost-trivializations is contractible.) The isomorphism (3.1) gives rise to the relative, or (fiberwise with respect to the projection to $L_x$) Fourier transforms which are quasi-inverse equivalences of triangulated categories

$$D^b(\tilde{B}', x')^{\tilde{L}} \xrightarrow{\text{FT}'^{\tilde{L}}} D^b(\tilde{B}'', x'')^{\tilde{L}}, \quad D^b(\tilde{B}', x')^{\tilde{L}, q} \xrightarrow{\text{FT}'^{\tilde{L}, q}} D^b(\tilde{B}'', x'')^{\tilde{L}, q}, \quad q \in k^*.$$  

They induce similar equivalences of abelian categories of twisted perverse sheaves.

**Definition 3.4.** — Let $q \in k^*$.

(a) An $L$-twisted, resp. $(L, q)$-twisted microlocal complex on $X$ is a datum $F$ consisting of:

1. An object $\tilde{F}^0$ of $D^b_{\text{const}}(\tilde{X})^{\tilde{L}}$, resp. of $D^b_{\text{const}}(\tilde{X})^{\tilde{L}, q}$
2. For each node $x \in D$ with the two branches $B', B''$ as above, isomorphisms

   $$\text{FT}'(\tilde{F}^0|_{\tilde{p}^{-1}(B')}) \to \tilde{F}^0|_{\tilde{p}^{-1}(B'')}, \quad \text{FT}'(\tilde{F}^0|_{\tilde{p}^{-1}(B'')}) \to \tilde{F}^0|_{\tilde{p}^{-1}(B')}$$

   inverse to each other.

(b) An $L$-twisted, resp. $(L, q)$-twisted microlocal sheaf is an $L$-twisted, resp. $(L, q)$-twisted microlocal complex such that $\tilde{F}^0$ is a perverse sheaf on $\tilde{L}^0$.

As before, for any finite subset $A \subset X$ of smooth points we denote by $\mathcal{D}M^L(X, A)$, resp. $\mathcal{D}M^L_q(X, A)$ the pre-triangulated dg-category formed by $L$-twisted, resp. $(L, q)$-twisted microlocal complexes $F$ on $X$ such that $\tilde{F}^0$ has locally constant cohomology outside of the preimage of $A$ in $\tilde{L}^0$. By
\[ \mathcal{M}^\ell(X, A), \text{ resp. } \mathcal{M}^{\ell,q}(X, A) \] we denote the full (abelian) subcategory in 
\[ D\mathcal{M}^\ell(X, A), \text{ resp. } D\mathcal{M}^{\ell,q}(X, A) \] formed by \( q \)-twisted microlocal sheaves.

C. Calabi-Yau properties

Theorem 1.7 generalizes to the twisted case as follows.

**Theorem 3.5.** — Assume \( X \) is a compact nodal curve with a duality 
structure, and \( (X_i)_{i \in I} \) be its irreducible components. Let \( \mathcal{L} \) be a line bundle 
on \( X \) with an almost-trivialization on a neighborhood of each node. Then:

(a) \( D\mathcal{M}^\ell(X, \emptyset) \) is a Calabi-Yau category of dimension 3.
(b) For any \( q \in k^* \) we have that \( D\mathcal{M}^{\ell,q}(X, \emptyset) \) is a Calabi-Yau category 
of dimension 2.

**Example 3.6.** — If \( X \) is a smooth projective curve of genus \( g \), then part 
(a) corresponds to the Poincaré duality on the compact 3-manifold \( \mathcal{L}^\circ / \mathbb{R}_+^* \), 
the circle bundle on \( X \) associated to \( \mathcal{L} \).

**Sketch of proof of Theorem 3.5.** — It is obtained by arguments similar 
to those for Theorem 1.7. That is, for any two objects \( \mathcal{F}, \mathcal{G} \) of the 
category \( D\mathcal{M}^\ell(X, \emptyset) \) resp. \( D\mathcal{M}^{\ell,q}(X, \emptyset) \) we introduce a constructible complex 
\( \mathcal{M}\text{Hom}^\ell(\mathcal{F}, \mathcal{G}) \) resp. \( \mathcal{M}\text{Hom}^{\ell,q}(\mathcal{F}, \mathcal{G}) \) whose complex of global sections over 
\( X \) is identified with \( R\text{Hom}(\mathcal{F}, \mathcal{G}) \) in the corresponding category. The statement 
then follows from canonical identifications

\[
\mathbb{D}\mathcal{M}\text{Hom}^\ell(\mathcal{F}, \mathcal{G}) \cong \mathcal{M}\text{Hom}^\ell(\mathcal{G}, \mathcal{F})[3], \\
\mathbb{D}\mathcal{M}\text{Hom}^{\ell,q}(\mathcal{F}, \mathcal{G}) \cong \mathcal{M}\text{Hom}^{\ell,q}(\mathcal{G}, \mathcal{F})[2].
\]

These identifications are obtained by comparing the bifunctor \( \mathcal{M}\text{Hom}^\ell \) with 
the bifunctor \( \mu\text{Hom} \) of [23] applied to constructible complexes on manifolds 
of the form \( \mathcal{L}^\circ|_Z \), where \( Z \) is a unibranched subset of \( X \).

4. Multiplicative preprojective algebras

A. The definitions

We recall the definition of multiplicative preprojective algebras, following [14] [45].

**Convention 4.1.** — There is a very close correspondence between:

(1) \( k \)-linear categories \( \mathcal{C} \) with finitely many objects.
Microlocal sheaves and quiver varieties

(2) Their total algebras

\[ \Lambda_C = \bigoplus_{x, y \in \text{Ob}(C)} \text{Hom}_C(x, y). \]

For instance, each object \( x \in C \) gives an idempotent \( 1_x \in \Lambda_C \), left \( \Lambda_C \)-modules are the same as covariant functors \( C \to \text{Vect}_k \), and so on. For this reason we will not make a notational distinction between objects of type (1) and (2), thus, for example, speaking about objects of an algebra \( \Lambda \) and morphisms between them (meaning objects and morphisms of a category \( C \) such that \( \Lambda = \Lambda_C \)).

Let \( \Gamma \) be a quiver, i.e., finite oriented graph, with the set of vertices \( I \) and the set of arrows \( E \), so we have the source and target maps \( s, t : E \to I \). We fix a total ordering \( < \) on \( E \).

Definition 4.2. — Let \( q = (q_i)_{i \in I} \in (\mathbb{C}^*)^I \). The multiplicative preprojective algebra \( \Lambda^q(\Gamma) \) is defined by generators and relations as follows:

(0) \( \text{Ob}(\Lambda^q(\Gamma)) = I \). In particular, for each \( i \in I \) we have the identity morphism \( 1_i : i \to i \).

(1) For each arrow \( h \in E \) there are two generating morphisms \( a_h : s(h) \to t(h) \) and \( b_h : t(h) \to s(h) \). We impose the condition that

\[ 1_{t(h)} + a_h b_h : t(h) \to t(h), \quad 1_{s(h)} + b_h a_h : s(h) \to s(h) \]

are invertible, i.e., introduce their formal inverses.

(2) We further impose the following relations: for each \( i \in I \),

\[ \prod_{h \in E : t(h) = i} (1_i + a_h b_h) \prod_{h \in E : s(h) = i} (1_i + b_h a_h)^{-1} = q_i 1_i, \]

where the factors in each product are ordered using the chosen total order \( < \) on \( E \).

It was proven in [14, Th. 1.4] that up to an isomorphism, \( \Lambda^q(\Gamma) \) is independent on the choice of the order \( < \), as well as on the choice of orientation of edges of \( \Gamma \).

B. Microlocal sheaves on rational curves

Let now \( X \) be a compact nodal curve over \( \mathbb{C} \) with the set of components \( X_i, i \in I \). We then have the intersection graph \( \Gamma_X \) of \( X \). By definition, this is an un-oriented graph with the set of vertices \( I \) and as many edges from \( i \) to \( j \) as there are intersection points of \( X_i \) and \( X_j \). In particular, for \( i = j \) we put as many loops as there are self-intersection points of \( X_i \). We now
choose an orientation of $\Gamma_X$ and an ordering of the arrows in an arbitrary way, thus making it into a quiver, so that the above constructions apply to $\Gamma_X$. Note that an orientation of $\Gamma_X$ is the same as an orientation of $X$ in the sense of §2A.

Let $\mathcal{L}$ be a line bundle on $X$. We keep the notation of §3. Let $d_i = \deg(\varpi^*_i \mathcal{L}) \in \mathbb{Z}$. For $q \in k^\times$ we denote $q^{\deg(\mathcal{L})} = (q^{d_i})_{i \in I}$.

**Theorem 4.3.** Assume that all the components $X_i$ are rational, i.e., the normalizations $\tilde{X}_i$ are isomorphic to $\mathbb{P}^1$. Then the category $\mathcal{M}_{\mathcal{L},q}(X,\emptyset)$ is equivalent to the category of finite-dimensional modules over $\Lambda^{\deg(\mathcal{L})}(\Gamma_X)$.

**C. Perverse sheaves on a disk: the $(\Phi, \Psi)$-description**

The proof of Theorem 4.3 is based on a conceptual interpretation of the factors $1_i + a_h b_h$ and $(1_i + b_h a_h)^{-1}$ entering the defining relations of $\Lambda^2(\Gamma)$. We observe that such expressions describe the monodromies of perverse sheaves on a disk.

More precisely, let $B$ be an open disk in the complex plane containing a point $y$. Let $\overline{B}$ be an “abstract” closed disk containing $B$ as its interior. We denote $\text{Perv}(B, y)$ the category of perverse sheaves on $B$ smooth everywhere except possibly $y$. Note that for any $\mathcal{F} \in \text{Perv}(B, y)$, the restriction of $\mathcal{F}$ to $B - \{y\}$ is a local system in degree 0 and so extends, by direct image, to a local system on $\overline{B} - \{y\}$. So we can think of $\mathcal{F}$ as a complex of sheaves on $\overline{B}$, whose restriction to $\overline{B} - \{y\}$ is quasi-isomorphic to a local system in degree 0. In particular, for each $z \in \overline{B} - \{y\}$ we have a single vector space $\mathcal{F}_z$, the stalk of $\mathcal{F}$ at $z$.

We have the following classical result [4] [19].

**Proposition 4.4.** — (a) Let $\mathcal{J}$ be the category of diagrams of finite-dimensional $k$-vector spaces

$$
\Phi \xrightarrow{a} \mathcal{F} \xrightarrow{b} \Psi
$$

such that the operator $T_{\Psi} = 1_\Psi + ab$ is invertible. For such a diagram the operator $T_{\Phi} = 1_\Phi + ba$ is invertible as well. The category $\text{Perv}(B, y)$ is equivalent to $\mathcal{J}$.

(b) Explicitly, an equivalence in (a) is obtained by choosing a boundary point $z \in \partial B$ and joining it with a simple arc $K$ with $y$. After such choices the vector spaces corresponding to $\mathcal{F} \in \text{Perv}(B, y)$ are found as

$$
\Psi = \Psi(\mathcal{F}) = \mathcal{F}_z = \mathbb{H}^0(K - \{y\}, \mathcal{F}), \quad \Phi = \Phi(\mathcal{F}) = \mathbb{H}^1_K(B, \mathcal{F}).
$$
The operator $T_\Psi$ is the anti-clockwise monodromy of the local system $\mathcal{F}|_{B - \{y\}}$ around $y$. □

The space $\Psi(\mathcal{F})$ and $\Phi(\mathcal{F})$ are referred to as the spaces of nearby and vanishing cycles of $\mathcal{F}$ at $y$ (with respect to the choice of an arc $K$).

**D. Fourier transform in the $(\Phi, \Psi)$-description**

Let $L$ be a 1-dimensional $\mathbb{C}$-vector space, $L^* = \text{Hom}_\mathbb{C}(L, \mathbb{C})$ be the dual space, with the canonical pairing

$$(z, w) \mapsto \langle z, w \rangle : L \times L^* \longrightarrow \mathbb{C}.$$ 

Let $K$ be a half-line in $L$ originating at 0, and $K^* = \{w \in L^* : \langle z, w \rangle \in \mathbb{R}_{\geq 0}, \forall z \in K\}$ be the dual half-line in $L^*$. We can consider $K$ as a simple arc in $L$ joining 0 with the infinity of $L$, and similarly with $K^*$. Therefore the choices of $K$ and $K^*$ give identifications of the categories $\text{Perv}(L, 0)$ and $\text{Perv}(L^*, 0)$ with the categories of diagrams as in Proposition 4.4.

**Proposition 4.5. —** Under the identifications of Proposition 4.4, the Fourier-Sato transform $\text{FT} : \text{Perv}(L, 0) \longrightarrow \text{Perv}(L^*, 0)$ corresponds to the functor $\text{FT}_J$ which takes

$$\begin{cases} \Phi \xrightarrow{a \quad b} \Psi \xleftarrow{a' \quad b'} \Phi \end{cases} \mapsto \begin{cases} \Phi \xrightarrow{a' \quad b'} \Psi \xleftarrow{a \quad b} \Phi \end{cases},$$

where $(a', b')$ are related to $(a, b)$ by the “cluster transformation”

$$\begin{cases} a' = -b, \\ b' = a(1 + ba)^{-1}. \end{cases}$$

□

**Corollary 4.6. —** In the situation of Proposition 4.5 we have

$$1 + a' b' = (1 + ba)^{-1}.$$ 

Note that this corollary prevents us from having a naive statement of the kind “Fourier transform interchanges $\Phi$ with $\Psi$ and $a$ with $b$”.

**Proof of Proposition 4.5. —** We first establish the identifications

$$\Psi(\text{FT}(\mathcal{F})) \simeq \Phi(\mathcal{F}). \quad (4.1)$$

Let $K^\dagger \subset L$ be the half-plane formed by $z$ such that $\Re(z, w) \geq 0$ for each $w \in K^*$. From the definition of FT, see [23], §3.7 and the fact that $\mathcal{F}$ is...
\(C^*\)-monodromic, we see that \(\Psi(FT(\mathcal{F}))\), i.e., the stalk of \(FT(\mathcal{F})\) at a generic point of the ray \(K^*\), is equal to the vector space \(H^1_K(L, \mathcal{F})\). But \(K^\dagger\) contains \(K\) and can be contracted to it without changing the cohomology with support for any \(\mathcal{F} \in \text{Perv}(L, 0)\). This means that \(\Psi(FT(\mathcal{F})) \simeq H^1_K(L, \mathcal{F}) = \Psi(\mathcal{F})\).

Next, we prove the Corollary 4.6. Note that rotating \(K\) in \(L\) anti-clockwise results in rotating \(K^*\) in \(L^*\) clockwise. So the monodromy on \(\Phi(\mathcal{F})\) obtained by rotating \(K\) in the canonical way given by the complex structure (i.e., anti-clockwise), is the inverse of the monodromy on \(\Psi(FT(\mathcal{F})) = \Phi(\mathcal{F})\) obtained by rotating \(K^*\) in the same canonical way (i.e., also anti-clockwise). This establishes the corollary.

We now prove Proposition 4.5 in full generality by using the approach of [4]. We identify \(\text{Perv}(L, 0)\) with \(\mathcal{J}\) throughout. Note that \(m = (T_\Phi, T_\Psi)\) defines an automorphism of the identity functor of \(\mathcal{J} = \text{Perv}(L, 0)\) called the monodromy operator. Further, \(\text{Perv}(L, 0)\) splits into a direct sum of abelian categories \(\text{Perv}(L, 0) = \text{Perv}(L, 0)_u \oplus \text{Perv}(L, 0)_n\).

Here \(m\) acts unipotently on every object \(\mathcal{F} \in \text{Perv}(L, 0)_n\) (equivalently, on \(\Phi(\mathcal{F}), \Psi(\mathcal{F})\) for \(\mathcal{F} \in \text{Perv}(L, 0)_u\), while \(1 - m\) is invertible on every object \(\mathcal{F} \in \text{Perv}(L, 0)_n\).

We construct the isomorphism claimed in Proposition 4.5 separately for \(\mathcal{F} \in \text{Perv}(L, 0)_u\) and \(\mathcal{F} \in \text{Perv}(L, 0)_n\).

Assume first that \(\mathcal{F} \in \text{Perv}(L, 0)_n\). Notice that for \(\mathcal{F} \in \text{Perv}(L, 0)_n\) the maps \(a : \Phi(\mathcal{F}) \to \Psi(\mathcal{F})\) and \(b : \Psi(\mathcal{F}) \to \Phi(\mathcal{F})\) are invertible. This means that either of the two functors \(\mathcal{F} \mapsto (\Psi(\mathcal{F}), T_\Psi)\), \(\mathcal{F} \mapsto (\Phi(\mathcal{F}), T_\Phi)\) is an equivalence between \(\text{Perv}(L, 0)_n\) and the category of vector spaces with an automorphism which does not have eigenvalue one. Thus in this case it suffices to construct a functorial isomorphism \(\Phi(\mathcal{F}) \simeq \Psi(FT(\mathcal{F}))\) sending the automorphism \(T_\Phi\) to \(T^{-1}_\Psi\). This reduces to Corollary 4.6.

We now consider \(\mathcal{F} \in \text{Perv}(L, 0)_u\). Notice that the category \(\text{Perv}(L, 0)_u\) has, up to isomorphism, two irreducible objects, \(\mathbb{L}_0 = k_0[-1]\) and \(\mathbb{L}_1 = k_L\) (the sky-scraper at zero and the constant sheaf). Let \(\Pi_0, \Pi_1\) be projective covers of \(\mathbb{L}_0, \mathbb{L}_1\), which are projective objects in the category of pro-objects \(\text{Pro}(\text{Perv}(L, 0)_u) \subset \text{Fun}(\text{Perv}(L, 0)_u, \text{Vect}_k)^{\text{op}}\).

They are defined uniquely up to an isomorphism. Moreover, any exact functor from \(\text{Perv}(L, 0)_u\) to vector spaces sending \(\mathbb{L}_1\) (resp. \(\mathbb{L}_0\)) to zero and \(\mathbb{L}_0\) (resp. \(\mathbb{L}_1\)) to a one dimensional space is isomorphic, in the sense of viewing pro-objects as functors above, to \(\Pi_0\) (resp. \(\Pi_1\)). This means that there exist...
isomorphisms of functors $\mathrm{Perv}(L,0) \to \mathrm{Vect}_k$

$$\Hom(\Pi_0, -) \cong \Phi, \quad \Hom(\Pi_0, -) \cong \Psi.$$  

We fix such isomorphisms.

Proposition 4.4 implies that $\mathrm{End}(\Pi_0) \cong k[[m-1]] \cong \mathrm{End}(\Pi_1)$ while each of the spaces $\Hom(\Pi_0, \Pi_0), \Hom(\Pi_0, \Pi_1)$ is a free rank one module over $k[[m-1]]$ generated respectively by elements $a, b$.

Since $\mathrm{FT}$ interchanges $L_0$ and $L_1$, we have

$$\mathrm{FT}(\Pi_0) \cong \Pi_1, \quad \mathrm{FT}(\Pi_1) \cong \Pi_0. \quad (4.2)$$

Furthermore, the isomorphism (4.1) sending $m\mathcal{F}$ to $m^{-1}_{\mathrm{FT}(\mathcal{F})}$ shows that for some (hence for any) choice of the isomorphisms $\mathrm{FT}(\Pi_0) \cong \Pi_1$ the automorphism $\mathrm{FT}(m)$ of the left hand side corresponds to the automorphism $m^{-1}$ of the right hand side. It follows that an isomorphism $\mathrm{FT}(\Pi_1) \cong \Pi_0$ also sends $\mathrm{FT}(m)$ to $m^{-1}$. We can choose the isomorphisms (4.2) in such a way that the map $\mathrm{FT}(a)$ becomes compatible with $-b$. This is clear since both elements generate the corresponding free rank one modules over $k[[m-1]]$. Then we see that $\mathrm{FT}(b)$ corresponds to $a(1 + ba)^{-1}$, this implies the statement. $\square$

Remark 4.7. — In the last paragraph of the proof we made a choice of isomorphisms (4.2) satisfying certain requirements. We have earlier constructed an isomorphism of functors (4.1). Combining it with the canonical isomorphism $\mathrm{FT}^2(\mathcal{F}) = (-1)^*(\mathcal{F})$ we can (upon making a binary choice of a homotopy class of a path connecting the ray $K$ to the ray $-K$) produce a canonical isomorphism $\Psi(\mathcal{F}) \cong \Phi(\mathrm{FT}(\mathcal{F}))$. These two isomorphism of functors yield isomorphisms of representing objects. We do not claim however that these isomorphisms satisfy our requirements. They provide another (isomorphic but different) functor on the category of linear algebra data of Proposition 4.4; it may be interesting to work it out explicitly.

Remark 4.8. — In the case $k = \mathbb{C}$ one can deduce the proposition from the infinitesimal description $\mathrm{Perv}(\mathbb{C}, 0) \simeq \mathcal{J}$ (Proposition 2.5), where the Fourier transform functor $\mathrm{FT}\mathcal{J} : \mathcal{J} \to \mathcal{J}$ is given by Corollary 2.6:

$$\{ E \xrightarrow{u} v \to F \} \mapsto \{ E' = F' \xleftarrow{u'} v' \to F' = E \}, \quad u' = v, v' = -u. \quad (4.3)$$

Since both $\mathcal{J}$ and $\mathcal{J}$ describe $\mathrm{Perv}(\mathbb{C}, 0)$, we get an identification $\mathcal{J} \to \mathcal{J}$ which was given explicitly by Malgrange [29, (II.3.2)] as follows:

$$\{ E \xrightarrow{u} v \to F \} \mapsto \{ \Phi = E \xleftarrow{a} b \to \Psi = F \}$$

$$\begin{cases}
    a = u, \\
    b = \varphi(vu) \cdot v, \quad \varphi(z) = (e^{2\pi iz} - 1)/z.
\end{cases} \quad (4.4)$$
By inverting (4.4) (i.e., finding $u$ and $v$ through $a$ and $b$), and then applying (4.4) to $u', v'$ given by (4.3), we get an object $\{ \Psi \xrightarrow{a'} \Phi \}$ which turns out to be isomorphic to $\{ \Psi \xrightarrow{a} \Phi \}$ by conjugation with an explicit invertible function of $1_{\Phi} + ba$.

E. Proof of Theorem 4.3

We start with an almost obvious model case of one projective line $Y \simeq \mathbb{P}^1$. Suppose we are given a point $z \in Y$ which will serve as an “origin” and a further set of $N$ points $A = \{y_1, \cdots, y_N\}$ which we position on the boundary of a closed disk $B$ containing $z$, in the clockwise order. Choose a system of simple arcs $K_\nu$ joining $z$ with $y_\nu$ and not intersecting outside of $z$. Let $\mathcal{L}$ be a line bundle of degree $d$ on $\mathbb{P}^1$ and let $q \in k^*$. 

**Lemma 4.9.** — The category $\text{Perv}^{(\mathcal{L}, q)}(Y, A)$ is equivalent to the category of diagrams consisting of vector spaces $\Psi, \Phi_1, \cdots, \Phi_N$ and linear maps

$$\{ \Phi_\nu \xrightarrow{a_\nu} \Psi \}, \; \nu = 1, \cdots, N,$$

such that each $1_{\Psi} + a_\nu b_\nu$ is invertible and

$$\prod_{\nu=1}^{N} (1_{\Psi} + a_\nu b_\nu) = q^d 1_{\Psi}.$$

**Proof.** — We first consider the untwisted case: $q = 1$ or, equivalently, no $\mathcal{L}$. In this case the statement follows at once from Proposition 4.4.4. Indeed, choose thin neighborhoods $U_\nu$ of $K_\nu$ (thus containing $z$ and $y_\nu$, which are topologically disks and let $U = \bigcup U_\nu$. We can assume that $Y$ is, topologically, a disk as well. An object $\mathcal{F} \in \text{Perv}(Y, A)$ can be seen as consisting of perverse sheaves $\mathcal{F}_\nu$ on $U_\nu$ which are glued together into a global perverse sheaf on $Y$. Each $\mathcal{F}_\nu$ is described by a diagram $\{ \Phi_\nu \xrightarrow{a_\nu} \Psi_\nu \}$. To glue the $\mathcal{F}_\nu$ together, we need, first, to identify all the $\Psi_\nu$ with each other, i.e., with a single vector space $\Psi$. This will give a perverse sheaf $\mathcal{F}_U$ on $U$. In order for $\mathcal{F}_U$ to extend to a perverse sheaf on $Y = \mathbb{C}\mathbb{P}^1$, it is necessary and sufficient that the monodromy of $\mathcal{F}_U$ along the boundary $\partial U$ of $U$ be trivial, in which case the extension is unique up to a unique isomorphism.

To identify this condition explicitly, let $\gamma_\nu$ be a loop in $Y$ beginning at $z$, going towards $y_\nu$ along $K_\nu$, then circling around $y_\nu$ anti-clockwise and
returning back to $z$ along the same path. Then $\partial U$ can be represented, up to homotopy, by the composite loop $\gamma = \gamma_1 \gamma_2 \cdots \gamma_N$ and the monodromy of $\mathcal{F}_\nu$ around $\gamma_\nu$ is $1 + a_\nu b_\nu$.

In the twisted case, choose a trivialization of $\mathcal{L}$ over $U$, so that we have the projections

$$ U \leftarrow \mathcal{L}^0|_U \xrightarrow{\beta} \mathbb{C}^* $$

Let $\tilde{z}$ be the vector in the fiber of $\mathcal{L}$ over $z$ such that $\beta(\tilde{z}) = 1$. Let $\tilde{\gamma} = \gamma \times \{1\} \subset U \times \mathbb{C}^* \simeq \mathcal{L}^0|_U$ be the lift of $\gamma$ with respect to the trivialization. Since $\gamma$ does not meet $A$, we can regard $\tilde{\gamma}$ as a loop in $\mathcal{L}^0|_{Y - A}$, beginning and ending at $\tilde{z}$.

Note that the line bundle $\mathcal{L}$ is trivial over $Y - A$ as well, and so

$$ \pi_1(\mathcal{L}^0|_{Y - A}, \tilde{z}) = \mathbb{Z} \cdot \zeta, $$

where $\zeta$ is the counterclockwise loop in the fiber $\mathcal{L}^0|_z$. Under this identification, the element represented by $\tilde{\gamma}$, is equal to $d \cdot \zeta$.

Now, using our trivialization, we have an equivalence

$$ M : \text{Perv}(U, A) \longrightarrow \text{Perv}(\mathcal{L}, q)(U, A), \quad \mathcal{F} \mapsto \alpha^* \mathcal{F} \otimes_k \beta^* \mathcal{E}_q, $$

where $\mathcal{E}_q$ is the 1-dimensional local system on $\mathbb{C}^*$ with monodromy $q$. An object $\mathcal{F}$ of $\text{Perv}(U, A)$ is described by a diagram of

$$ \{ \Phi, \xrightarrow{a_\nu} \Psi \}, \quad \nu = 1, \cdots, N $$

as before. The possibility of extending $M(\mathcal{F})$ from $\mathcal{L}^0|_U$ to the whole of $\mathcal{L}^0$ is equivalent to the monodromy around $\zeta \in \pi_1(\mathcal{L}|_{Y - A}, \tilde{z})$ being equal to $q \cdot 1$. In view of the equality $\tilde{\gamma} = d \cdot \zeta$, this gives precisely the condition of the lemma. $\square$

The proof of Theorem 4.3 is now obtained by gluing together the descriptions of Lemma 4.9, using Proposition 4.5 and Corollary 4.6.

More precisely, we apply the lemma to each $(Y_i, A_i)$, $i \in I$, where the $Y_i = \tilde{X}_i \xrightarrow{\psi_i} X$, $i \in I$ are the components of the normalization $\tilde{X}$ of $X$, and $A_i = \tilde{D} \cap \tilde{X}_i$. We recall that $\tilde{D} \subset \tilde{X}$ is the preimage of the set of nodes $D \subset X$. We put $\mathcal{L}_i = \omega_i^* \mathcal{L}$ so that $d_i = \deg(\mathcal{L}_i)$.

Choose an orientation of the intersection graph $\Gamma = \Gamma_X$, or, equivalently, an ordering $(x', x'')$ of the pair of preimages of each node $x \in D$. We will
label these preimages by the arrows $h$ of $\Gamma$, i.e., denote them by

$$x_h' \in A_{s(h)} \subset Y_{s(h)}, \quad x_h'' \in A_{t(h)} \subset Y_{t(h)}, \quad h \in E.$$ 

Thus $A_i$ consists of

$$x_h', \quad s(h) = i \quad \text{and} \quad x_h'', \quad t(h) = i.$$ 

We choose a base point $z_i$ in each $Y_i$ and position the elements of $A_i$ on the boundary of a disk around $z_i$, so that, in the clockwise order, we have first the $x_h'', t(h) = i$ (according to the order $<$ on $E$) and then the $x_h', s(h) = i$ (again according to $<$). We join $z_i$ with the elements of $A_i$ simple arcs meeting only at $z_i$.

An object $F_i \in \Perv(L_i, q_i)(Y_i, A_i)$ is then described by a diagram consisting of one space $\Psi_i$ together with spaces $\Phi_{x_h'}$, $s(h) = i$ and $\Phi_{x_h''}$, $t(h) = i$ together with the maps

$$\{ \Phi_{x_h'} \xrightarrow{a_h'} \Psi_i \}, \quad s(h) = i, \quad \{ \Phi_{x_h''} \xrightarrow{a_h''} \Psi_i \}, \quad t(h) = i$$

so that the condition of the lemma reads:

$$\prod_{t(h)=i} (1 + a_h'' b_h'') \prod_{s(h)=i} (1 + a_h' b_h') = q^{d_i} \cdot 1. \quad (4.5)$$

In order to glue the $F_i$ into one twisted microlocal sheaf on $X$, we need to specify an identification of Fourier transforms at each node $x$. This means that $\Psi_i$ (which is identified with the space of nearby cycles of $F_i$ at each $x_h'$, $s(h) = i$ and each $x_h''$, $t(h) = i$) becomes identified with the space of vanishing cycles of $F_{t(h)}$ at $x_h''$ for $s(h) = i$ and of $F_{s(h)}$ at $x_h'$ for $t(h) = i$.

Therefore all the linear algebra data reduce to the vector spaces $V_i = \Psi_i$ and linear operators

$$a_h : V_{s(h)} = \Psi_{s(h)} \simeq \Phi_{x_h'}(F_{t(h)}) \xrightarrow{a_h'} \Psi_{t(h)} = V_{t(h)},$$

$$b_h : V_{t(h)} = \Psi_{t(h)} \xrightarrow{b_h''} \Phi_{x_h''}(F_{t(h)}) \simeq \Psi_{s(h)} = V_{s(h)},$$

where $\simeq$ stands for the identifications given by the Fourier transform. This means that we do not use the simply primed $a_h'$, $b_h'$, expressing them through $a_h'', b_h''$ by Proposition 4.5.

After this reduction, the conditions (4.5) coincide, in view of Corollary 4.6, with the defining relations of the multiplicative preprojective algebra.

□
5. Preprojective algebras for general nodal curves

Theorem 4.3 can be extended to the case of arbitrary compact nodal curves by introducing an appropriate analog of preprojective algebras (PPA). In this section we present this analog and discuss possible further generalizations to differential graded (dg-) case and their consequences for the symplectic structure of moduli spaces.

Throughout the paper we use the notation 
\[ [\alpha, \beta] = \alpha \beta^{-1} \beta^{-1} \]
to denote the group commutator.

A. Higher genus PPA

Let \( X \) be a compact nodal curve over \( \mathbb{C} \). As before we denote by \( D \) the set of nodes of \( X \), by \( X_i, i \in I \) the irreducible components of \( X \) and by \( \tilde{X}_i \subset \tilde{X} \xrightarrow{\varpi} X \) the normalizations of \( X_i \) and \( X \). Let \( \mathcal{L} \) be a line bundle on \( X \) and \( \tilde{\mathcal{L}} = \varpi^* \mathcal{L} \). We denote by:

\[ g_i = \text{the genus of } \tilde{X}_i, \quad d_i = \deg(\tilde{\mathcal{L}}|_{\tilde{X}_i}), \quad \tilde{D}_i = \varpi^{-1}(D) \cap \tilde{X}_i. \]

We choose an orientation of \( X \), i.e., a total order \( x' < x'' \) on each 2-element set \( \varpi^{-1}(x), x \in D \), see §2A.

For each node \( x \in D \) we denote by \( s(x) \in I \) the label of the irreducible component containing \( x' \), and by \( t(x) \) the label of the component containing \( x'' \). We also choose a total order on the set \( D \).

**Definition 5.1.** — Let \( X, \mathcal{L} \) as above be given and \( q \in k^* \). The preprojective \((X, \mathcal{L})\)-algebra \( \Lambda^{\mathcal{L},q}(X) \) is defined by generators and relations as follows:

(0) Objects \( i \in I \).

(1) For each node \( x \in D \), two generating morphisms \( a_x : s(x) \to t(x) \) and \( b_x : t(x) \to s(x) \). We impose the condition that

\[ 1_{t(h)} + a_h b_h : t(h) \to t(h), \quad 1_{s(h)} + b_h a_h : s(h) \to s(h) \]

are invertible, i.e., introduce their formal inverses.

(1') For each \( i \in I \) there are generating morphisms

\[ \alpha^i, \beta^i, \quad i = 1, \ldots, g_i, \]

which are required to be invertible.

(2) For each \( i \in I \) we impose a relation
Here the factors in the first two products are ordered using the chosen total order < on D.

Examples 5.2. — (a) If all $X_i$ are rational, then $\Lambda^{L,q}(C)$ reduces to the multiplicative preprojective algebra associated to the quiver $\Gamma_X$, and parameters $q^{d_i}$, see §4.

(b) If $X$ is smooth irreducible of genus $g > 0$, then the fundamental group $\pi_1(X)$ has a universal central extension $\tilde{\pi}_1(X)$ given by generators and relations as follows

$$\tilde{\pi}_1(X) = \left\langle \alpha_1, \cdots, \alpha_g, \beta_1, \cdots, \beta_g, q \bigg| \prod_{\nu=1}^{g} [\alpha_\nu, \beta_\nu] = q, [\alpha_i, q] = [\beta_i, q] = 1 \right\rangle.$$ 

In this case $\Lambda^{L,q}(X)$ is a quotient of the group algebra of $\tilde{\pi}_1(X)$ by the relation $q = q^d$.

Theorem 5.3. — The abelian category $\mathcal{M}^{L,q}(X, \emptyset)$ is equivalent to the category of finite-dimensional modules over $\Lambda^{L,q}(X)$.

B. Proof of Theorem 5.3

It is similar to that of Theorem 4.3. We first consider the following model case.

Let $Y$ be a smooth, compact, irreducible curve of genus $g$ together with finite subset $A = \{y_1, \cdots, y_N\} \subset Y$. Let $L$ be a line bundle over $Y$ of degree $d$. Define a $k$-algebra $\Lambda^{L,q}(Y, A)$ by generators and relations as follows;

(0) Objects $\psi, \phi_1, \cdots, \phi_N$.
(1) Generating morphisms

$$a_\lambda : \phi_\lambda \to \psi, \quad b_\lambda : \psi \to \phi_\lambda, \quad \lambda = 1, \cdots, N; \quad \alpha_\nu, \beta_\nu : \psi \to \psi, \quad \nu = 1, \cdots, g.$$ 

We require that

$$1_\psi + a_\lambda b_\lambda, \quad 1_{\phi_\lambda} + b_\lambda a_\lambda, \quad a_\nu, b_\nu, h_\mu$$

be invertible, i.e., introduce their formal inverses.
Microlocal sheaves and quiver varieties

(2) One relation
\[
\prod_{\lambda=1}^{N} (1_\psi + a_\lambda b_\lambda) \prod_{\nu=1}^{g} [\alpha_\nu, \beta_\nu] = q^d 1_\psi.
\]

**Lemma 5.4.** — The abelian category \( \text{Perv}^L(Y,A) \) is equivalent to the category of finite-dimensional \( \Lambda^L(Y,A) \)-modules.

**Proof.** — Completely analogous to that of Lemma 4.9. We choose a base point \( p \in Y - A \), realize \( \alpha_i \) and \( \beta_i \) as the standard A- and B-loops based at \( p \) and choose simple arcs \( K_\lambda \) jointing \( p \) with \( y_\lambda \) so that they do not intersect except at \( p \) and follow each other in the clockwise order. Conjugating with \( K_\lambda \) a small loop around \( y_\lambda \), we get a loop \( h_\lambda \) based at \( p \), and we can choose the \( K_\lambda \) to follow the system of \( \alpha_i \), \( \beta_i \) in the clockwise order so that in \( \pi_1(Y - A, p) \) we have the relation
\[
\prod_{\lambda=1}^{N} h_\lambda \prod_{\nu=1}^{g} [\alpha_\nu, \beta_\nu] = 1.
\]

Let \( D \) be a disk containing all the paths \( K_\lambda \), so \( L \) is trivial over \( D \). The lemma is obtained by gluing the category of perverse sheaves on \( D \) and that of (twisted) local systems on \( X - D \). \( \square \)

Theorem 5.3 is now obtained by gluing the descriptions of Lemma 5.4 for \((Y,A) = (\tilde{X}_i, \tilde{D}_i)\) for various \( i \). \( \square \)

C. Remarks on derived PPA

The algebra \( \Lambda^{L,q}(X) \) has a derived analog. This is a dg-algebra \( L\Lambda^{L,q}(X) \) with the same generators \( a_x, b_x, \alpha_x^i, \beta_x^i \) as \( \Lambda^{L,q}(X) \) (considered in degree 0) with the same conditions of invertibility but instead of imposing relations in Definition 5.1, we introduce new free generators of degree \(-1\) whose differentials are put to be the differences between the LHS and RHS of the relations. The symbol \( L \) is used to signify the left derived functor. Thus \( \Lambda^{L,q}(X) \) is the 0th cohomology algebra of \( L\Lambda^{L,q}(X) \).

It seems very likely that the triangulated category \( D\mathcal{M}^{L,q}(X) \) can be identified with the derived category formed by finite-dimensional dg-modules over \( L\Lambda^{L,q}(X) \) (with quasi-isomorphisms inverted). In view of Theorem 1.7 we can then expect that \( L\Lambda^{L,q}(X) \) is a Calabi-Yau dg-algebra of dimension 2. In other word, we expect that, denoting \( L = L\Lambda^{L,q}(X) \), there is a quasi-isomorphism of \( L \)-bimodules
\[
\gamma : L \rightarrow L^\dagger := R\text{Hom}_{L \otimes L^{\text{op}}}(L, L \otimes L^{\text{op}})[2], \quad \text{such that} \quad \gamma = \gamma^\dagger[2], \quad (5.1)
\]
see [20], Def. 3.2.3.
In general, $L\Lambda^L_{\mathcal{L},q}(X)$ is not quasi-isomorphic to $\Lambda^L_{\mathcal{L},q}(X)$, which explains the following example.

**Example 5.5.** — Let $X$ be the union of two projective lines meeting transversely, let $\mathcal{L}$ be trivial and $q = 1$. Then $\mathcal{D}\mathcal{M}(X, \emptyset)$ is a Calabi-Yau category of dimension 2, while $\mathcal{M}(X, \emptyset)$ has infinite cohomological dimension. Indeed, $\mathcal{M}(X, \emptyset)$ is identified with the category of modules over the multiplicative preprojective algebra corresponding to the quiver $A_2$; this algebra has two objects 1, 2 generating morphisms $a : 1 \to 2$ and $b : 2 \to 1$ subject to the relations $ab = ba = 0$.

We can also define the universal higher genus PPA (derived as well as non-derived) by replacing $q \in \mathbb{k}^*$ in the above by an indeterminate $q$ and working over the Laurent polynomial ring $\mathbb{k}[q^{\pm 1}]$. We denote the corresponding (dg-) algebras by $L\Lambda^L_{\mathcal{L}}(X)$ and $\Lambda^L_{\mathcal{L}}(X)$.

Because of the 1-dimensionality of $\mathbb{k}[q^{\pm 1}]$, we expect that $L\Lambda^L_{\mathcal{L}}(X)$, considered as a dg-algebra over $\mathbb{k}$, is 3-Calabi-Yau, rather than 2-Calabi-Yau.

**Example 5.6.** — If $X$ is a smooth projective curve of genus $g > 0$, then $\Lambda^L_{\mathcal{L}}(X)$ is the group algebra of the fundamental group of $\mathcal{L}^\circ$. Now, $\mathcal{L}^\circ$ is homotopy equivalent to a circle bundle over $X$, which is a compact, aspherical, oriented 3-manifold. By [20], Cor. 6.1.4 this implies that $\Lambda^L_{\mathcal{L}}(X)$ is a (non-dg) 3-Calabi-Yau algebra. Further, in this case $L\Lambda^L_{\mathcal{L}}(X)$ is quasi-isomorphic to $\Lambda^L_{\mathcal{L}}(X)$ by [20], Thm. 5.3.1.

### D. Remarks on moduli spaces

Assume $\text{char}(\mathbb{k}) = 0$. We would like to view the symplectic nature of (multiplicative) quiver varieties as yet another manifestation of the following general principle, which also encompasses the approaches of [21] and [32] to local systems (resp. coherent sheaves) on topological (resp. K3 or abelian) surfaces.

**2-Calabi-Yau principle 5.7.** — If $\mathcal{C}$ is a Calabi-Yau category of dimension 2, then $\mathcal{M}$, the “moduli space” of objects in $\mathcal{C}$, has a canonical symplectic structure. After identifying the “tangent space” to $\mathcal{M}$ at the point corresponding to object $E$, with $\text{Ext}^1_{\mathcal{C}}(E, E)$, the symplectic form is given by the cohomological pairing

$$\text{Ext}^1_{\mathcal{C}}(E, E) \otimes \text{Ext}^1_{\mathcal{C}}(E, E) \xrightarrow{\cup} \text{Ext}^2_{\mathcal{C}}(E, E) \xrightarrow{\text{tr}} \mathbb{k},$$

where $\text{tr}$ corresponds, via the Calabi-Yau isomorphism, to the embedding $\mathbb{k} \to \text{Hom}_C(E, E)$. 

- 502 -
This principle, along with a generalization to $N$-Calabi-Yau categories for any $N$, was formulated in [25] §10 and made precise in a formal neighborhood context. A wider, more global, interpretation would be as follows.

"Space": understood in the sense of derived algebraic geometry [27] [41], as a derived stack. Informally, a derived stack $\mathcal{Y}$ can be seen as a nonlinear (curved) analog of a cochain complex of $k$-vector spaces, in the same sense in which a manifold can be seen as a curved analog of a single vector space. In particular, for a $k$-point $y \in \mathcal{Y}$ we have the tangent dg-space $T_{y\mathcal{Y}}$, which is a cochain complex. The amplitude of $\mathcal{Y}$ is an integer interval $[a, b]$ such that $H^i T_{y\mathcal{Y}} = 0$ for $i \not\in [a, b]$ and all $y$. Given a morphism $f : Y \to Z$ of smooth affine algebraic varieties over $k$ and a $k$-point $z \in Z$, we have the derived preimage $Rf^{-1}(z)$, which is a derived stack (scheme) of amplitude $[0, 1]$, see [15] for elementary treatment.

"Moduli": understood as the derived stack $\mathcal{M}_C$ of moduli of objects in a dg-category $C$ defined in [40]. Under good conditions on $C$, each object $E$ gives a $k$-point $[E] \in \mathcal{M}_C$ and we have the Kodaira-Spencer quasi-isomorphism

$$T_{[E]} \mathcal{M}_C \simeq R\text{Hom}_C(E, E)[1].$$

"Symplectic": understood in the sense of [34]. That is, the datum of a symplectic form on a derived stack $\mathcal{Y}$ includes not only pairings on the tangent dg-spaces $T_{y\mathcal{Y}}$ but also higher homotopies for the de Rham differentials of such pairings.

"2-Calabi-Yau": In order for the approach of [25] to be applicable, even at the formal level, we need not only canonical identifications $R\text{Hom}(E, F)^* \simeq R\text{Hom}(F, E)[2]$ but a finer structure: an $S^1$-equivariant functional on the Hochschild cohomology of $C$ inducing these identifications, see [39], p. 70.

For instance, if $C$ is the derived category of dg-modules over a dg-algebra $L$, we need an isomorphism $\gamma$ as in (5.1), i.e., $L$ should have a structure of a Calabi-Yau dg-algebra in the sense of [20]. For the categories of deformation quantization modules, Hochschild cohomology classes of this nature were constructed in [24] Thm. 6.3.1.

While there is every reason to expect the validity of Principle 5.7 in this setting, this has not yet been established. The case of $C = D\text{M}(X, \emptyset) = D^b_{\text{loc. const.}}(X)$ for a smooth compact $X$ follows from the results of [34], as in this case $\mathcal{M}_C$ is interpreted in terms of mapping stacks to the $(-2)$-shifted symplectic stacks $B\text{GL}_N$. This interpretation does not apply to $D\text{M}(X, \emptyset)$ for a general compact nodal curve $X$. So we cannot use Principle 5.7 to construct “symplectic moduli spaces of microlocal sheaves”. In the next section
we present an alternative, more direct approach via quasi-Hamiltonian reduction.

6. Framed microlocal sheaves and multiplicative quiver varieties

A. Motivation

Recall [33] that the original setting of Nakajima Quiver Varieties $M_\Gamma(V, W)$ involves two types of vector spaces associated to vertices $i$ of quiver $\Gamma$:

1. The “color” spaces $V_i$ which are gauged, i.e., we perform the Hamiltonian reduction by the group $GL(V) = \prod GL(V_i)$ in order to arrive at $M_\Gamma(V, W)$.
2. The “flavor” spaces $W_i$ which are fixed, in the sense that $M_\Gamma(V, W)$ depends on $W$ functorially. In particular, it has a Hamiltonian action of the group $GL(W) = \prod GL(W_i)$.

The setting of preprojective algebras (whose multiplicative version was reviewed in §4), corresponds to the case when $W_i = 0$.

In this section we explain a geometric framework allowing us to introduce such flavor spaces in a more general context of microlocal sheaves. For simplicity we restrict the discussion to untwisted microlocal sheaves.

B. Microlocal sheaves framed at $\infty$

Let $Y$ be a quasi-projective nodal curve over $\mathbb{C}$ with a duality structure. We assume that $Y = \overline{Y} - \infty$, where $\overline{Y}$ is a compact nodal curve and $\infty = \{\infty_j\}_{j \in J}$ is a finite set of smooth points. Let

$$Y^\partial = \text{Bl}_\infty(\overline{Y}) = Y \cup C, \quad C = \bigsqcup_{j \in J} C_j$$

be the real blowup of $\overline{Y}$ at $\infty$. Thus $Y^\partial$ is a compact topological space obtained by adding to $Y$ the circles $C_j$, so that each $C_j = S^1_{\infty_j} \overline{Y}$ is the circle of real directions of $\overline{Y}$ at $\infty_j$. Note that in a neighborhood of $C$, the space $Y^\partial$ is naturally a 2-dimensional oriented $C^\infty$-manifold with boundary $C$. We choose a base point $p_j$ in each $C_j$.

Any microlocal sheaf $\mathcal{F}$ on $Y$ is a local system in degree 0 near $\infty$. Thus it extends canonically (by direct image) to a complex of sheaves $\mathcal{F}^\partial$ on $Y^\partial$ which is a local system in degree 0 near $C$. In particular, it gives rise to finite-dimensional $k$-vector spaces $\mathcal{F}_{p_j}$, defined as the stalks of $\mathcal{F}^\partial$ at $p_j$. 

- 504 -
Microlocal sheaves and quiver varieties

We denote by

\[ m_j(F) : F_{p_j} \rightarrow F_{p_j} \]

the anti-clockwise monodromy of \( F \partial \) around \( C_j \).

**Definition 6.1.** — Let \( W = (W_j)_{j \in J} \) be a family of finite-dimensional \( k \)-vector spaces. By a \( W \)-framed microlocal sheaf on \( Y \) we mean a datum consisting of a microlocal sheaf \( F \in \mathcal{M}(Y, \emptyset) \) together with isomorphisms \( \phi_j : F_{p_j} \rightarrow W_j, j \in J \).

We denote by \( \mathcal{M}(Y)_W \) the category (groupoid) formed by \( W \)-framed microlocal sheaves on \( Y \) and their isomorphisms (identical on \( W \)).

**Proposition 6.2.** — Assume that \( Y \) is an affine nodal curve with a duality structure, i.e., there is at least one puncture on each irreducible component. Then:

(a) There exists a smooth affine algebraic \( k \)-variety \( \mathcal{M}(Y)_W \) (the moduli space of \( W \)-framed microlocal sheaves) such that isomorphism classes of objects of \( \mathcal{M}(Y)_W \) are in bijection with \( k \)-points of \( \mathcal{M}(Y)_W \).

(b) The group \( GL(W) = \prod GL(W_j) \) acts on \( \mathcal{M}(Y)_W \) by change of the framing. Taking the monodromies around the \( C_j \) gives an equivariant morphism (which we call the moment map)

\[ m = (m_j)_{j \in J} : \mathcal{M}(Y)_W \rightarrow GL(W). \]

**Proof.** — (a) We analyze the data of a \( W \)-framed microlocal sheaf directly on \( \tilde{X} \), as in the previous section. These data reduce to a collection of linear operators between the \( W_j \) such that certain expressions formed out of them are invertible but, since each \( \tilde{X}_i \) is affine, subject to no other relations. This means that \( \mathfrak{M}(Y)_W \) is realized as an open subset in the product of sufficiently many copies of affine spaces \( Hom(W_j, W_{j'}) \).

(b) Obvious. \( \square \)

**Example 6.3 (Smooth Riemann surface).** — (a) Let \( \overline{Y} \) be a smooth projective curve of genus \( g \). Choose one point \( \infty \in \overline{Y} \) and put \( Y = \overline{Y} - \{\infty\} \), so that \( |J| = 1 \). Accordingly, we choose one base point \( p \in Y \) near \( \infty \) in the sense explained above. A microlocal sheaf \( F \in \mathcal{M}(Y, \emptyset) \) is just a local system on \( Y \).

So we fix one vector space \( W \) and denote \( G = GL(W) \). A \( W \)-framed microlocal sheaf is just a homomorphism \( \pi_1(Y, p) \rightarrow G \). As well known, \( \pi_1(Y, p) \) is a free group on \( 2g \) generators \( \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_g \) which correspond to the \( a \)- and \( b \)-cycles on the compact curve \( \overline{Y} \). Therefore \( \mathfrak{M}(Y)_W = G^{2g} \) is
the product of $2g$ copies of $g$. The $G$-action on $\mathcal{M}(Y)_W$ is by simultaneous conjugation. The moment map has the form

$$m : G^{2g} \to G, \quad (A_1, \cdots, A_g, B_1, \cdots, B_g) \mapsto \prod_{\nu=1}^{g} [A_{\nu}, B_{\nu}],$$

so $m^{-1}(e) = \text{Hom}(\pi_1(\overline{Y}, \infty), G)$ is the set of local systems on the compactified curve, trivialized at $\infty$.

(b) More generally, let $Y$ be an arbitrary smooth curve, compactified to $\overline{Y}$ by a finite set of punctures $\infty_j, j \in J$. Then $\mathcal{M}(Y)_W$ is the space of representations of $\pi_1(Y, \{\infty_j\}_{j \in J})$, the fundamental groupoid of $Y$ with respect to the set of base points $\infty_j$. This is the setting of [3], §9.2, see also [8], Thm. 2.5.

**Example 6.4 (Coordinate cross).** — Let $Y = \{(x_1, x_2) \in \mathbb{A}^2 \mid x_1 x_2 = 0\}$ be the union of two affine lines meeting transversely. Then $\overline{Y}$ is the union of two projective lines meeting transversely and $\infty$ consists of two punctures. Accordingly, we have two marked points on $Y^\partial$, denote them $p_1$ and $p_2$. Given a family of two vector spaces $W = (W_1, W_2)$, the stack $\mathcal{M}(Y)_W$ is the affine algebraic variety known as the van den Bergh’s quasi-Hamiltonian space, see [43] and [8, §2.4]:

$$\mathcal{M}(Y)_W = \mathcal{B}(W_1, W_2) := \{ W_1 \xrightarrow{a} W_2 \mid 1 + ab \text{ is invertible} \}.$$ 

Note that $1 + ba$ is also invertible on $\mathcal{B}(W_1, W_2)$.

**Example 6.5 (Microlocal sheaves with framed $\Phi$).** — Let $X$ be a compact nodal curve with a duality structure, and $A \subset X$ be a finite subset of smooth points. Form a new curve $Y = X_A$, as in Proposition 1.6. Then $\mathcal{M}(Y)_W$ can be seen as the category parametrizing microlocal sheaves on $X$ which are allowed singularities at $A$, but are equipped with a $W$-framing of their vanishing cycles at each such singular point. To emphasize it, we denote this category by $\mathcal{M}(X, A)_W$.

**Example 6.6.** [Multiplicative quiver varieties]— We now specialize the above example further. Let $X$ be a compact nodal curve with irreducible components $X_i, i \in I$. Assume, as in §4, that each $X_i$ is a rational curve, i.e., that the normalization $\tilde{X}_i$ is isomorphic to $\mathbb{P}^1$. Choose the set $A$ consisting of precisely one smooth point $a_i$ on each $X_i$. Let $W = (W_i)_{i \in I}$ be a family of $k$-vector spaces. Thus the topological structure of $(X, A)$ is determined by the graph $\Gamma$ of intersections of irreducible components of $X$, in particular, $I$ is the set of vertices of $\Gamma$. We will write $X = X_\Gamma$ to indicate this dependence.

**Proposition 6.7.** — In the situation just described, $\mathcal{M}(X, A)_W$ is equivalent to the category which parametrizes linear algebra data consisting of:
Microlocal sheaves and quiver varieties

(1) Collections of vector spaces $V = (V_i)_{i \in I}$;
(2) Linear maps $a_h : V_{s(h)} \to V_{t(h)}$, $b_h : V_{t(h)} \to V_{s(h)}$, $h \in E$,
    $u_i : V_i \to W_i$, $v_i : W_i \to V_i$, $i \in I$,
such that all the maps
    $$(1 + a_h b_h), \quad (1 + b_h a_h), \quad (1 + u_i v_i), \quad (1 + v_i u_i)$$
are invertible, and
(3) For each $i \in I$ we have the identity
    $$(1_{V_i} + v_i u_i) \prod_{h \in E, t(h) = i} (1_{V_i} + a_h b_h) \prod_{h \in E, s(h) = i} (1_{V_i} + b_h a_h)^{-1} = 1_{V_i}.$$ These data are considered modulo isomorphisms of the $V_i$.

Proof. — Completely analogous to that of Theorem 4.3 and we leave it to the reader. □

The moduli spaces of semistable objects of $\mathcal{M}(X, A)_W$ (defined as GIT quotients) as well as their analogs for twisted sheaves are the multiplicative quiver varieties (MQV) as defined in [45].

Example 6.8 (Higher genus MQV). — In the interpretation of the previous example, we associated to a graph $\Gamma$ a nodal curve $X_{\Gamma}$ with all components rational. In particular, the number $g_i$ of loops at a vertex $i \in \Gamma$ was interpreted as the number of self-intersection points of the corresponding rational curve $X_i$. We can also associate to $\Gamma$ a nodal curve $X'_{\Gamma}$ in a different way, by taking the component $X'_i$ associated to $i$ to be of genus $g_i$ (and interpreting other edges of $\Gamma$ as intersection points of the $X'_i$). Choose the set $A$ to consist of one point on each irreducible component of $X'_\Gamma$. This defines a datum $(X'_{\Gamma}, A)$ uniquely up to a diffeomorphism. We will refer to the moduli spaces of objects of $\mathcal{M}(X'_{\Gamma}, A)_W$ (defined as GIT quotients) as higher genus multiplicative quiver varieties associated to $\Gamma$. Note that one can also consider their twisted versions, involving twisted microlocal sheaves.

C. Quasi-Hamiltonian $G$-spaces

Here we review the main points of the theory of group valued moment maps [3]. This theory has been interpreted in [35] in terms of Lagrangian intersections. For simplicity we work in the complex algebraic situation, not that of compact Lie groups.
Let $G$ be a reductive algebraic group over $\mathbb{C}$, with Lie algebra $\mathfrak{g}$. We denote by
\[
\theta^L = g^{-1}dg, \quad \theta^R = (dg)g^{-1} \in \Omega^1(G, \mathfrak{g})
\]
the standard left and right invariant $\mathfrak{g}$-valued 1-forms on $G$.

We fix an invariant symmetric bilinear form $(-, -)$ on $\mathfrak{g}$. It gives rise to the bi-invariant scalar 3-form (the Cartan form)
\[
\eta = \frac{1}{12}(\theta^L, [\theta^L, \theta^L]) = \frac{1}{12}(\theta^R, [\theta^R, \theta^R]) \in \Omega^3(G).
\]

For a $G$-manifold $M$ and $\xi \in \mathfrak{g}$ we denote by $\partial_\xi$ the vector field on $M$ corresponding to $\xi$ by the infinitesimal action.

**Definition 6.9.** [3].— A quasi-Hamiltonian $G$-space is a smooth algebraic variety $M$ with $G$-action, together with a $G$-invariant 2-form $\omega \in \Omega^2(M)^G$ and a $G$-equivariant map $m : M \to G$ (the group valued moment map) such that:

1. (QH1) The differential of $\omega$ satisfies $d\omega = -m^*\chi$.
2. (QH2) The map $m$ satisfies, for each $\xi \in \mathfrak{g}$, the condition
   \[
i\partial_\xi \omega = \frac{1}{2}m^*(\theta^L + \theta^R, \xi).
   \]
   Here $(\theta^L + \theta^R, \xi)$ is the scalar 1-form on $G$ obtained by pairing the $\mathfrak{g}$-valued form $\theta^L + \theta^R$ and the element $\xi \in \mathfrak{g}$ via the scalar product $(-, -)$.
3. (QH3) For each $x \in M$, the kernel of the 2-form $\omega_x$ on $T_xM$ is given by
   \[
   \ker(\omega_x) = \{ \partial_\xi(x), \xi \in \ker(\text{Ad}_{m(x)} + 1) \}.
   \]

Given a quasi-Hamiltonian $G$-space $(M, \omega, m)$, the quasi-Hamiltonian reduction of $M$ by $G$ is, classically [3], the quotient
\[
M/G = m^{-1}(e)^{\text{sm}}/G,
\]
where $m^{-1}(e)^{\text{sm}}$ is the smooth locus of the scheme-theoretic preimage $m^{-1}(e)$ or, more precisely, the open part formed by those points $m$, for which $d_m m$ is surjective.

**Theorem 6.10.** [3].— For any quasi-Hamiltonian $G$-space $M$ the quotient $M/G$ is a smooth orbifold (i.e., Deligne-Mumford stack) with a canonical symplectic structure. $\square$

**Remark 6.11.** — Using the language of derived stacks allows one to formulate Theorem 6.10 in a more flexible way, without restricting to the locus of smooth points. More precisely, we can form the smooth derived stack of amplitude $[-1, 1]$
\[
[M/G]^{\text{der}} = Rm^{-1}(e)/G.
\]
Here $Rm^{-1}(e)$ is the derived preimage of $e$, a smooth derived scheme of amplitude $[0,1]$. Further, the symbol $-\//G$ means stacky quotient by $G$. The analog of Theorem 6.10 is then that $[M\//G]^{\text{der}}$ is a symplectic derived stack which contains $M\//G$ as an open part, see [35].

The following is the main result of this section.

**Theorem 6.12.** — Let $Y$ be an affine nodal curve, and $W = (W_j)$ as before. The smooth algebraic variety $\mathfrak{M}(Y)_W$ has a natural structure of a quasi-Hamiltonian $GL(W)$-space with the moment map $m = m_W$ given by the monodromies (Proposition 6.2(b)).

**Remark 6.13.** — This result provides a more direct approach to the “moduli space” of microlocal sheaves on a compact nodal curve, in particular, to the symplectic structure on this space.

Indeed, the set-theoretic quotient $m^{-1}_W(e)/GL(W)$ parametrizes microlocal sheaves $\mathcal{F}$ on the compact curve $\overline{Y}$ such that the dimensions of the stalk of $\mathcal{F}$ at $\infty_j$ is equal to $\dim W_j$. Thus we can define the derived stack

$$\mathfrak{M}(\overline{Y}, \emptyset) = \bigsqcup_W [\mathfrak{M}(Y)_W \//GL(W)]^{\text{der}},$$

the disjoint union over all possible choices of $(\dim W_j)_{j \in J}$. Alternatively, one can consider the Poisson variety obtained as the spectrum of the algebra of $GL(W)$-invariant functions on $\mathfrak{M}(Y)_W$, cf. [8], Prop. 2.8.

In the case of a smooth curve $Y$, see Example 6.3(b), a proof of Theorem 6.12 was given in [3, §9.3] using a procedure called fusion which allows one to construct complicated quasi-Hamiltonian spaces from simpler ones. We use the same strategy but allow one more type of “building block” in the fusion construction.

**D. Fusion of quasi-Hamiltonian spaces**

We now briefly review the necessary concepts.

**Theorem 6.14 ([3]).** — Let $M$ be a quasi-Hamiltonian $G \times G \times H$-space, with moment map $m = (m_1, m_2, m_3)$. Let $G \times H$ act on $M$ via the diagonal embedding $(g,h) \mapsto (g,g,h)$. Then $M$ with the 2-form

$$\omega' = \omega + \frac{1}{2}(m^*_1\theta^L, m^*_2\theta^R)$$

and the moment map

$$m' = (m_1 \cdot m_2, m_3) : M \to G \to H$$
is a quasi-Hamiltonian $G \times H$-space, called the (intrinsic) fusion of the $G \times G \times H$-space $M$.

Remark 6.15. — The geometric meaning of the fusion is that the two copies of $G$ from $G \times G \times H$ are “attached” to the two of the tree boundary components of a 3-holed sphere, and the new diagonal copy of $G$ from $G \times H$ is then “read off” on the remaining component, see [3], Ex. 9.2 and [8] §2.2. Thus, in the case of smooth curves, fusion directly corresponds to gluing Riemann surfaces out of simple pieces. We will extend this to nodal curves.

The extrinsic fusion of a quasi-Hamiltonian $G \times H_1$-space $M_1$ and a $G \times H_2$-space $M_2$ is the $G \times H_1 \times H_2$-space $M_1 \boxtimes M_2$ which is the fusion of the $G \times H_1 \times G \times H_2$-space $M_1 \times M_2$ along the embedding $G \hookrightarrow G \times G$.

We will use the following three building blocks.

Examples 6.16. — (a) (Double of $G$: annulus). Given $G$ as before, its double is the quasi-Hamiltonian $G \times G$-space $D(G) = G \times G$ with coordinates $a, b \in G$, the $G \times G$-action given by

$$(g_1, g_2)(a, b) = (g_1 a g_2^{-1}, g_2 b g_1^{-1}),$$

the moment map given by

$$m_D : D(G) = G \times G \longrightarrow G \times G, \quad (a, b) \mapsto (ab, a^{-1}, b^{-1})$$

and the 2-form given by

$$\omega_D = \frac{1}{2} (a^* \theta^L, b^* \theta^R) + \frac{1}{2} (a^* \theta^R, b^* \theta^L).$$

For a vector space $V$ and $G = GL(V)$, this space is identified with $\mathfrak{M}(Y)_W$, where $Y$ is a 2-punctured sphere and $W = (V, V)$ associates $V$ to each puncture. The surface with boundary $Y^\partial$ is an annulus.

(b) Intrinsically fused double: holed torus. With $G$ as before, its intrinsically fused double $D(G)$ is the quasi-Hamiltonian $G \times G$-space $G \times G$ obtained as the fusion of the $G \times G$-space $D(G)$. For a vector space $V$ and $G = GL(V)$, this space is identified with $\mathfrak{M}(Y)_V$ where $Y$ is a 1-punctured elliptic curve. The surface $Y^\partial$ is a 1-holed torus.

(c) The space $\mathcal{B}(W_1, W_2)$: cross. To treat nodal curves, we add the third type of building blocks: the varieties $\mathcal{B}(W_1, W_2)$, see Example 6.4. Again, this is a known quasi-Hamiltonian $GL(W_2) \times GL(W_2)$-space [43] [44] with moment map

$$(a, b) \mapsto ((1 + ab)^{-1}, 1 + ba) \in GL(W_2) \times GL(W_1)$$

- 510 -
and the 2-form
\[ \omega = \frac{1}{2} \left( \text{tr} W_2 (1 + ab)^{-1} da \wedge db - \text{tr} W_1 (1 + ba)^{-1} db \wedge da \right). \]

As we saw in Example 6.4, it is identified with \( \mathcal{M}(Y)_{W_1, W_2} \), where \( Y \) is a coordinate cross. The topological space \( Y^{\partial} \) is the union of two disks meeting at one point.

Let now \( Y \) be an affine nodal curve. The topological space \( Y^{\partial} \) can then be decomposed into elementary pieces of types (a)-(c) in the above examples, joined together by several 3-holed spheres.

Let \( W = (W_j)_{j \in J} \) be given. Note that for \( \mathcal{M}(Y)_W \) to be non-empty, the numbers \( N_j = \dim W_j \) should depend only on the irreducible component of \( Y \) containing \( \infty_j \). This means that to each boundary component of each elementary piece we can unambiguously associate a group \( GL(N_j) \) and so form the corresponding quasi-Hamiltonian space of type (a)-(c) above. Taking the product of these corresponding quasi-Hamiltonian spaces and performing the fusion along the 3-holed spheres, we get a quasi-Hamiltonian space which is identified with \( \mathcal{M}(Y)_W \). This proves Theorem 6.12.

Remarks 6.17. (a) It would be interesting to construct the 2-form on \( \mathcal{M}(Y)_W \) more intrinsically, in terms of a cohomological pairing, using some version of Poincaré-Verdier duality for cohomology with support on the “nodal surface with boundary” \( Y^{\partial} \). For smooth \( Y \) such a construction follows from the results of \([12]\) and \([35]\). In these papers, the moment map \( \mathcal{M}(Y)_W \to GL(W) \) given by the monodromy around the boundary was given a Lagrangian structure (using Poincaré duality); in particular, it has an underlying 2-form which pulls back to the required form on \( \mathcal{M}(Y)_W \).

(b) By applying further fusion to \( \mathcal{M}_Y(W) \) (with \( Y \) affine), we can obtain pseudo-Hamiltonian structures on the (higher genus) multiplicative quiver varieties from Examples 6.6 and 6.8.

7. Further directions

A. (Geometric) Langlands correspondence for nodal curves

Since microlocal sheaves without singularities form a natural analog of local systems for nodal curves, it would be interesting to put them into the framework of the Langlands correspondence. In particular, for a compact nodal curve \( X \) it would be interesting to have a derived equivalence between the de Rham version (cf. §2) of the “Betti-style” derived stack \( \mathcal{M}(X, \emptyset) \) and
some other moduli stack $\mathcal{B}$ of “coherent” nature, generalizing the moduli stack of vector bundles on a smooth curve. A potential candidate for $\mathcal{B}$ is provided by the moduli stack of Riemann surface quiver representations in the sense of [13].

Note that the concept of microlocal sheaves makes sense for nodal curves $X$ over $\mathbb{F}_q$. So one can expect that their $L$-functions (appropriately defined) have, for projective nodal curves $X$, properties similar to those of $L$-functions of local systems on smooth projective curves over $\mathbb{F}_q$.

One can even consider arithmetic analogs of nodal curves, obtained by gluing the spectra of rings of integers in number fields along closed points. An example is provided by the spectrum of the group ring $\mathbb{Z}\left[\mathbb{Z}/p\right]$, where $p$ is a prime. This scheme is the union of $\text{Spec}(\mathbb{Z})$ and $\text{Spec}(\mathbb{Z}[\sqrt{1}])$ meeting transversely at the point $(p)$, cf. [31], §2.

B. Multiplicative quiver varieties and mirror symmetry

Let $\Gamma$ be a finite graph, possibly with loops, and $\mathbb{M}_{V,W}(X_{\Gamma})^q$ be the corresponding higher genus multiplicative quiver varieties, see Example 6.8. Here $q = (q_i) \in (\mathbb{C}^\times)^I$ is a vector of twisting parameters. We expect that the varieties $\mathbb{M}_{V,W}(X_{\Gamma})^q$ are mirror dual to the ordinary (“additive”) Nakajima quiver varieties for $\Gamma$.

In particular, we expect that $\mathbb{M}_{\Gamma}(V,W)^q$ is singular if and only if the point $q$ lies in the singular locus of the equivariant quantum connection for the ordinary quiver variety. Here, equivariance is in reference to the action of an algebraic torus which acts on the quiver variety scaling the symplectic form by a nontrivial character. See [30], where this connection as well as its singularities, have been computed.

C. Borel/unipotent reduction and cluster varieties

It would be interesting to extend the approach of [18] from local systems on smooth curves to microlocal sheaves on nodal curves. That is, in the situation of §6B we can choose any number of marked points $p_{j,\nu}$ on each boundary component $C_j$ of $Y_{\partial}$. After this we can consider microlocal sheaves $\mathcal{F}$ together with a Borel or unipotent reduction of the structure group at each $p_{j,\nu}$ (recall that each restriction $\mathcal{F}|_{C_j}$ is a local system).

The appearance of a cluster-type transformation in Proposition 4.5 suggests that the moduli spaces of microlocal sheaves as above may provide interesting examples of cluster varieties. These varieties may be related to

- 512 -
the classification of irregular DQ-modules on a symplectic surface with support in a nodal curve. Indeed, spaces with Borels on sectors have appeared in the classical (Deligne 1978) description of Stokes structures. So one can expect a unified theory of “wild microlocal sheaves”, combining our approach with that of [7][8][9].

D. 3-dimensional generalization

The datum of a smooth compact curve over $\mathbb{C}$ (topologically, an oriented surface) $X$ and a finite set of points $A \subset X$ has the following 3-dimensional analog.

We consider a compact oriented $C^\infty$ 3-manifold $M$ and a link in $M$, i.e., a collection $L = \{C_a\}_{a \in A}$ of disjoint embedded circles (knots). We have then a stratification of $M$ into the $C_a$ and the complement of their union. Denote the $D^b_L(M)$ the category of complexes of sheaves on $M$, constructible with respect to this stratification. For $L = \emptyset$, it is a 3-Calabi-Yau category by Poincaré duality. For arbitrary $L$, it has a natural abelian subcategory $\text{Perv}(M, L)$ of “perverse sheaves”. Given any surface $X \subset M$ meeting $L$ transversely, an object $\mathcal{F} \in \text{Perv}(M, L)$ gives a perverse sheaf on $X$, smooth outside $X \cap L$.

One can obtain 3d analogs of compact nodal curves (“nodal 3-manifolds”) by identifying several compact 3-manifolds pairwise along some knots. For example, we can glue two such manifolds $M'$ and $M''$ (say, two copies of the sphere $S^3$) by identifying a knot $C' \subset M'$ with a knot $C'' \subset M''$. As the normal bundle $T_C M$ of a knot $C$ in an oriented 3-manifold $M$ is trivial, we can choose a duality structure, i.e., an identification of $T_{C'} M'$ with $T_{C''} M''$, and then set up the formalism of microlocal sheaves and complexes. This should lead to interesting 3-Calabi-Yau categories and to $(-1)$-shifted symplectic stacks parametrizing their objects.

3-Calabi-Yau categories of the form $D\mathcal{M}^L(X, \emptyset)$, see Theorem 3.5(a), correspond to a particular type of nodal 3-manifolds: circle bundles over nodal curves over $\mathbb{C}$.

Appendix A. Notations and conventions.

We fix a base field $k$. All sheaves will be understood as sheaves of $k$-vector spaces, similarly for complexes of sheaves.

All topological spaces we consider will be understood to be homeomorphic to open sets in finite CW-complexes, in particular, they are locally compact.
and of finite dimension. For a space $X$ we denote by $\text{Sh}(X)$ the category of sheaves of $k$-vector spaces on $X$. We denote by $D^b \text{Sh}(X)$ the bounded derived category of $\text{Sh}(X)$. We will consider it as a pre-triangulated category \cite{10}, i.e., as a dg-category enriched by the complexes $R\text{Hom}(\mathcal{F}, \mathcal{G})$, so that $H^0R\text{Hom}(\mathcal{F}, \mathcal{G})$ is the “usual” space of morphisms from $\mathcal{F}$ to $\mathcal{G}$ in the derived category. Alternatively, we can view it as a stable $\infty$–category by passing to the dg-nerve \cite{26} \cite{28} \cite{17}.

We denote by $D^b_{\text{cc}}(X) \subset D^b \text{Sh}(X)$ the full subcategory of cohomologically constructible complexes \cite{23} and by $\mathbb{D} = \mathbb{D}_X$ the Verdier duality functor on this subcategory \cite{23, §3.4}. Thus, if $X$ is an oriented $C^\infty$-manifold of real dimension $d$, and $\mathcal{F}$ is a local system on $X$ (put in degree 0), then $\mathbb{D}(\mathcal{F}) = \mathcal{F}^\bullet[d]$, where $\mathcal{F}^\bullet$ is the dual local system. In general, for any compact space $X$ and any $\mathcal{F} \in D^b_{\text{cc}}(X)$ we have \textit{Poincaré-Verdier duality}, which is the canonical identification of complexes of $k$-vector spaces with finite-dimensional cohomology, and consequently, of their cohomology spaces:

$$R\Gamma(X, \mathcal{F})^* \simeq R\Gamma(X, \mathbb{D}_X(\mathcal{F}));$$
$$H^i(X, \mathcal{F})^* \simeq H^{-i}(X, \mathbb{D}_X(\mathcal{F})).$$ \hfill (A.1)

Let $X$ be a complex manifold. We denote by $D^b_{\text{constr}}(X) \subset D^b_{\text{cc}}(X)$ the derived category of bounded complexes of sheaves on $X$ with $\mathbb{C}$-constructible cohomology sheaves. The functor $\mathbb{D}_X$ preserves this subcategory. We denote by $\text{Perv}(X) \subset D^b_{\text{constr}}(X)$ the subcategory of perverse sheaves. The conditions of perversity are normalized so that a local system on $X$ put in degree 0, is perverse. Thus $\text{Perv}(X)$ has the perfect duality given by

$$\mathcal{F} \mapsto \mathcal{F}^\bullet := \mathbb{D}(\mathcal{F})[-2\dim_{\mathbb{C}}(X)].$$
